The report contains much else that is valuable, e.g. a discussion on the relation of tsetse problems to game and to reforestation, and a terse account by POTTS of the relation between fly and vegetation.

The formal recommendations of the conference appear to have been written in a conservative and somewhat platitudinous mood. Among the more interesting ones, there is a proposal for the rapid exchange of information between territories, both on the distribution of tsetse and trypanosomiasis and on the progress of measures of control. A list of Government organizations which should be kept informed has been drawn up, and the Government of the Colony of Mozambique is invited to approach the French and Belgian authorities asking them to participate in the exchange of information. It is also desirable that bibliographies and summaries of work published should be circulated. [It does not appear to have been pointed out at the conference that some of these functions have been carried out not unsuccessfully by the *Tropical Diseases Bulletin* and its predecessor the *Sleeping Sickness Bulletin*, since the year 1908.] There are also proposals for the use of uniform symbols in mapping the distribution of tsetse and trypanosomiasis. Such symbols are illustrated at the end of the Report. P. I. Burton

SANDGROUND, J. H. with the technical aid of Rosey MAYNARD. Experimental Studies of an Old Strain of *Trypanosoma gambiense*. I. The Enhancement of its Virulence and the relationship of this Phenomenon to the Species of Polymorphic Trypanosomes of Africa. *Ann Trop Med & Parasit* 1947, Dec v 41, Nos 3/4 293-305, 2 figs on 1 pl. [27 refs]

While the trypanosomes of the *brucei* group are morphologically indistinguishable and therefore constitute only a single species on clinical and epidemiological grounds they are referable to distinct categories corresponding to *T. gambiense*, *T. rhodesiense* and *T. brucei*. The first two parasites differ not only in the degree of pathogenicity to man but also in their response to treatment with drugs and in virulence to laboratory rodents. In the last respect *T. rhodesiense* resembles *T. brucei* more closely than it resembles *T. gambiense*.

In the present paper, an account is given of the experimental transformation of a typical *T. gambiense* into a strain highly pathogenic for laboratory rodents. The original 'Nzale' strain was brought to the United States from the Belgian Congo where it was isolated from a wild *Glossina palpalis* into a guinea pig, and passed through other guinea pigs, as well as through man. Using a standard infection, produced by intraperitoneal inoculation of blood containing one million trypanosomes the author studied the behaviour of "Nzale" strain in laboratory rodents. The infection in guinea pigs was symptomatic with an average duration of 78 days. In rabbits, mice and hamsters its course was even more benign usually terminating in spontaneous recovery, with trypanosomes rarely appearing in the blood. Adolescent rats (35-50 days

old) rarely showed signs of infection while trypanosomes were present in the blood in varying numbers, the average survival time of these animals being 163 days.

Since such benign infections in rodents were unsuitable for chemotherapeutic tests, it was decided to increase the virulence of this strain. Whereas rapid syringe-passages through rodents splenectomy and blockade of the reticulo-endothelial system, failed to produce the desired effect success was obtained by inoculation of nursing rats 17 days old, with a heavy suspension of trypanosomes from an adult rat. Some of the young rats were heavily infected after 3 days, their average survival time being 32 days. Further passages through young rats brought about a gradual increase in the virulence until the 7th serial passage, when the duration of the infection was reduced to three days. Infection of older rats with the modified strain described as "V" resulted in their death after 4 days while the original "Nzale" strain retained its non-pathogenic character throughout the experiments. The behaviour of "Nzale" and "V" strains in rodents was compared in parallel experiments. In mice infected with "V" strain, there was progressive parasitaemia terminating in the death of the animals by the 5th day while those infected with "Nzale" strain showed scanty trypanosomes or none at all and the majority of the animals survived. All rats infected with "V" strain died within 7 days, while those infected with "Nzale" had scanty infections and died at irregular periods between the 25th and 95th days of infection. The average survival time of hamsters infected with "V" strain was 18.8 days these animals also showed evidence of involvement of the central nervous system. On the other hand, the "Nzale" strain produced no visible signs of infection in hamsters. In contrast to the avirulent effect of "Nzale" strain, "V" strain killed rabbits within 60 days, with symptoms of acute disease manifested by lymphadenopathy and atrophy of cardiac muscles. In guinea pigs the contrast between the two strains is less marked.

In addition to enhanced virulence, the "V" strain of *T. g. marseus* revealed changes in susceptibility to drugs and in general behaviour which were indistinguishable from those of a strain of *T. brucei* studied in the same laboratory. Like *T. brucei* it is sensitive to antypol (Bayer 205) and to stilbamidine but is not affected by the highest tolerated doses of tryparsamide.

The stability of strain "V" was demonstrated by failure to produce it after attenuation after inoculation of small doses of trypanosomes into adult rat and after passages through various other rodents. On the other hand the experiment of enhancing the virulence of "Nzale" strain by inoculation of young rats was successfully repeated several times.

In conclusion, the author discusses the bearing of his experiment on the question regarding the phylogenetic relations of trypanosomes of the *brucei* group. Since in these experiments by controlled and reproducible laboratory procedures, a typically gambiense trypanosome has been modified to produce a strain characteristic in every way of *T. brucei* or of *T. hodesiensis* it is held that similar changes might occur under natural conditions. Furthermore the present findings seem to indicate that the age of the host might be a potent element in favouring the enhancement of virulence among trypanosomes. Consequently infection of young hosts may represent the means whereby virulent strains of the human trypanosomes of West Africa are produced in nature.

The author regards *T. g. marseus* and *T. hodesiensis* as mutant strains of a single species which the international zoological law of nomenclature would by reason of priority recognize as *T. brucei*. This view was previously expressed by the reviewer (see this Bulletin 1944: 41-150).

BESSEMANS, A, WITTEBOLLE, P & BAERT, H, Mlle Etude, par la micro-manipulation, de la virulence d'un ou de plusieurs trypanosomes et de granules de sang trypanosé [A Study by Micromanipulation of the Virulence of Single or Several Trypanosomes and of Granules in the Associated Blood] *Rev Belge Sci Méd* 1946, Oct, v 17, No 5, 284-9 [29 refs]

A review is given of previous attempts to infect animals by few or single trypanosomes. Infections produced by single trypanosomes have been reported by various workers during the past thirty years. The present work was carried out with an arsenic-resistant strain of *T. gambiense*, with a normal strain of *T. gambiense* and with a Belgian strain of *T. equiperdum*. By means of a micromanipulator, trypanosomes were isolated from citrated blood and injected subcutaneously into other animals. Eight guineapigs were inoculated with 1 to 20 trypanosomes from the arsenic-resistant strain of *T. gambiense*, no infections resulted. Similarly, nine other guineapigs were inoculated with one to fifty parasites from the ordinary strain of *T. gambiense*, none became infected. With the strain of *T. equiperdum*, transmission to mice was achieved in one of 36 animals inoculated with a single trypanosome. With 2-5 trypanosomes, about 8 per cent of a limited number of animals became infected. But even with as many as 50 to 200 trypanosomes, failure to infect often occurred. Twenty mice were inoculated with the granules which occur in the blood of animals with trypanosomiasis. None of these animals became infected. In other experiments the blood taken from guineapigs during the lytic stages of the infection was not infective for mice although apparently it contained many trypanosomes. *F Hawking*

MORACZEWSKI, S A & KELSEY, F E Distribution and Rate of Metabolism of Phosphorus Compounds in *Trypanosoma equiperdum* *J Infect Dis* 1948, Jan-Feb, v 82, No 1, 45-51, 1 fig [15 refs]

A study has been made of the phosphorus metabolism of *T. equiperdum* *in vitro* and *in vivo*, with the aid of P^{32} , a radioactive isotope of the element. In the *in vitro* investigations trypanosomes were isolated by centrifugation from the blood of infected rats and were then suspended in a saline-phosphate medium containing 2 per cent protein at pH 7.6 to 7.8 and maintained at 37.5°C. The motility of the trypanosomes was impaired by repeated washing and their total phosphorus content was reduced. In experiments with radioactive phosphorus the labelled element with an activity of 3 millicuries per mgm was added to the medium as phosphate, to give a concentration of 0.5 mgm phosphorus per cc. Total phosphorus was measured by chemical methods and radioactivity by means of a Geiger-Müller counter. A method based on that of SCHNEIDER (*J Biol Chem* 1945, v 161, 293) was used on aliquots of trypanosome suspensions to estimate the distribution of phosphorus in the acid-soluble, phospholipid, nucleic acid, and phosphoprotein fractions. In the *in vivo* experiments in which 10 mgm of labelled phosphorus, as neutral phosphate containing 20 millicuries of P^{32} , was given intraperitoneally to rats phosphorus was similarly estimated in the four different fractions of isolated trypanosomes in plasma and in homogenates of heart and liver. In view of the results of CHEN & GEILING (*Proc Soc Exper Biol & Med*, 1946, v 63, 486) who showed that a phosphorylating mechanism was concerned in the breakdown of glucose to pyruvic acid the authors believe that the acid-soluble fraction may contain the phosphorus compounds involved in this process. While the total P present in trypanosomes kept in presence of stable or radioactive phosphorus was similar, the distribution in the various

fractions was altered, as a result the authors believe of the greater concentration of phosphorus in the medium made necessary for the measurement of radioactivity. During *in vitro* experiments the trypanosomes became inactive and probably more permeable thus vitiating to some extent the measurement of phosphorus exchanges which the authors considered to be of negligible proportions. The exchanges in three of the fractions *in vivo* were very much greater than those *in vitro* when measured after injection of the infected animal with labelled phosphorus. The turnover was in fact greater in the case of the trypanosomes than in the host tissues and showed that the parasites could utilize the inorganic phosphorus present in plasma for the synthesis of organic compounds of this element.

STYKES, C. D., HADAWAY, A. B., BARLOW, F. & GALLEY, W. Field Experiments with DDT and Benzene Hexachloride against Tsetse (*Glossina palpalis*). *Bull. Entom. Res.* 1948, Feb., v 38, Pt 4 591-612, 4 maps, 3 text figs. & 3 figs. on 1 pl.

The five experiments described in this paper were performed in Uganda in 1946. Vegetation was sprayed with DDT and gammexane to a height of 6 feet. The first test took place on Nko, an unoccupied island of 100 acres in Lake Victoria, about a mile from the mainland, where the tsetse population was estimated to be 11,700. Gammexane (0.65 per cent gamma) in 50 per cent. kerosene and 50 per cent. cottonseed oil was applied by Four Oaks hand sprayers at a rate of 2 1/2 quarts per 1,000 square feet. The selected patches amounted approximately to 2 acres. The fly reduction was estimated at 56 per cent. over a period of 10 days, after which the numbers began to increase. After 4 weeks they had reached pre-treatment numbers. The spraying was then repeated and some additional areas were included. For a week afterwards the reduction in fly density was about 80 per cent., but rose again. Deposits of gammexane on leaf surfaces of samples of treated vegetation were low even one day after application.

Areas of vegetation on another island, Mbirumbwa, about a mile from the mainland, were similarly treated this time with DDT (5 per cent in 50 per cent. kerosene and 50 per cent. cottonseed oil). About 17 acres of total of 30 acres were treated. Reduction of fly was estimated at 60 per cent. for a week, then the numbers increased. There seemed to be an appreciable loss of insecticide through penetration of the leaves.

In a later test on the same island, four applications of DDT were made at intervals of 10 to 14 days. The selected areas of vegetation along the coast and in the centre of the island amounted to about 4 acres. From the 6th to the 13th week after the final application, no flies were seen or caught; then flies were captured. Again there was considerable loss of insecticide from leaf surfaces some 1 ft through rain.

The last experiment was made at Nkuruba, a peninsula of the mainland, where a linear distance of about 8,000 yards was treated. Four applications of DDT were made the first two concentrating on the part of DDT in the phloem.

used with an emulsifier) and two parts of lake water and the other two of 5 per cent DDT in deiselne. The movement of cattle and rainfall interfered with the trial to some extent, and as a result of the rainfall the growth of the vegetation was very rapid. The fly density was reduced by about 98 per cent but a week after the final application flies began to appear in fair numbers at some points. Insecticide deposits on sample papers and leaves were small, though the ATSO emulsion persisted for several weeks and gave fairly good kills. Deposits of 116 and 173 mgm per square foot on leaves of *Dracaena* gave kills of 100 per cent and 93 per cent respectively for 8 and 16 weeks afterwards. Deposits on hairy leaves gave negligible kills. The authors conclude that these rather laborious methods, even at excessive dosages, are not likely to eliminate *Glossina palpalis*. The experiments show that an insecticide is required that will not be absorbed by the vegetation, and that will not lose its toxicity, and a method will have to be devised that will give much greater coverage than can be achieved with small knapsack sprayers.

ARANJA, F S, DIAS, E & NOBREGA, G. O eletrocardiograma na cardiopatia crônica da doença de Chagas [The Electrocardiogram in Chronic Cases of Chagas's Disease] *Brasil-Médico* 1948, Feb 21 & 28, v 62, Nos 8/9, 51-2 English version 52-3

This appears to be a summary of a paper presented to or read at an Inter-American Congress of Cardiology, held in Mexico in October 1946, and based on investigations carried out in Minas Gerais. The authors studied 357 cases of chronic Chagas's disease and electrocardiographic alterations were found in 208 (58.2 per cent) of them. These included extrasystole of ventricular origin, A-V blockage of different types, intraventricular block, nearly always of the right branch bundle (90 out of 92), QRS changes with or without T-wave alterations. P-wave alterations usually transient, and, less commonly, auricular fibrillation. Arrhythmia was present in just over half (52.9 per cent) of those with abnormal electrocardiogram, usually ventricular in origin, and the authors maintain that extrasystoles persisting after effort point strongly to cardiac involvement in patients with Chagas's disease. A-V block was observed in 21.5 per cent of those showing ECG abnormalities and this is regarded as an early change, so much so that when this symptom is found in patients under 40 years of age, other, confirmatory, signs of Chagas's disease should be looked for. Another peculiarity is the suddenness with which changes may occur in the A-V and intraventricular conduction time. Alterations of the T-wave might be temporary and transient or permanent, like those seen in ischaemia of the anterior wall ("coronary T-wave"). If the former they would show progression and retrogression in cycles which varied in different patients. In ordinary cases of Chagas's disease auricular fibrillation is not common but when present is of bad import, as Chagas himself noted, if, however it is associated with arteriosclerosis it may react to quinidine and the prognosis is more favourable. Only slight changes are frequent in the P-wave, marked change is very rare [figures are not given].

LEISHMANIASIS

SHI LU CHANG & NEGERBON W. O. Studies on Hemoflagellates. III. The Specificity of Serological Reactions of *Leishmania donovani* vs. *L. brasiliensis*, *L. tropica* and *Trypanosoma cruzi*. *J. Infect. Dis.* 1947 Nov-Dec. v 81 No. 3 209-27 10 figs. on 2 pls. [17 refs.]

Employing the culture method described in an earlier paper [this *Bulletin*, 1947 v 44 1055] the authors have tested the serological reactions of two strains of *Leishmania donovani* and *Trypanosoma cruzi* and of one strain of *L. brasiliensis* and *L. tropica*. Guinea-pigs were immunized against *T. cruzi* by injecting them intraperitoneally with living organisms or with 0.5 to 2 cc. of the packed killed organisms, it being estimated that 1 cc. contained 2,500,000,000 flagellates. The organisms were killed with formalin which was added to the washed suspension of flagellates to give a concentration of 0.025 per cent. or by heat, an exposure to 50-55°C. being given for 20 minutes. For the leishmania, only living organisms were used for immunization. Blood was taken from the guinea-pigs by heart puncture after the 6th, 8th and 13th injections of antigen given at intervals of three to four days. Agglutination tests were carried out with various dilutions of serum, the microslide test with living organisms giving the best results. In all cases, the sera gave a good agglutination with the homologous organism but a weaker agglutination was always given with the other organisms.

Furthermore, with increased dilution of the sera, the heterologous agglutination disappeared first, the homologous agglutination persisting at a + reaction with dilutions of 1 in 1,280 to 1 in 2,560. In the complement-fixation tests, both a glycerinated antigen and one prepared by lyophilizing thoroughly washed organisms suspended in normal saline were used. No significant difference in the potency of these antigens was noted. In the precipitin reaction the ring test was found to be the most delicate. The lytic effect of antisera at low dilutions could not be eliminated with the leishmania, but could be in the case of the more resistant *T. cruzi*. Absorption of antiserum with homologous antigen removed the species as well as the cross-reacting antibodies, while absorption of antiserum with heterologous antigen removed all of the respective antibody part of the cross-reacting antibodies and reduced the agglutination titre against the homologous antigen organisms. Ghost cells gave the same reactions as living cells, but a lower titre of the homologous antigen. The general result of the observations is that the culture forms of the organisms tested have both species-specific and common antigen and that the specific antigen is predominant while the common antigen is probably a combination of several antigen components. FEVERS OF THE TYPHUS GROUP

REVOL, L., COUDERT, J. & MOREL, P. Etude de la moelle osseuse par ponction sternale de neuf cas de typhus exanthématique. Study of the Bone Marrow obtained by Sternal Puncture in Nine Cases of Exanthematic Typhus. *Bull. Soc. Path. E.* 1947 v 40 Nos 11-12, 479-82.

The authors give a brief summary of the scanty literature dealing with the changes found in the bone marrow in typhus fever and then describe the conditions found in nine cases studied at the height of the attack.

JADIN J & GIROUD P. Typhus exanthématique de l'Urundi, agglutination des rickettsiales. (*Exanthematic Typhus in Urundi (Belgian Congo); Rickettsial Agglutination.*) *Bull. Soc. Path. Exot.* 1947 v 40 No. 11/12, 414-16.

An epidemic of typhus fever occurred in Urundi in 1945-1946, and 23 sera of patients from various localities were tested by the rickettsial-agglutination reaction. Eighteen of these sera agglutinated epidemic typhus rickettsiae at much higher titres than murine-typhus rickettsiae and only one gave a reaction suggestive of murine infection, the response being a titre of 1-8 400 with murine rickettsiae against one of 1-3,200 with epidemic rickettsiae.

John H D Meigs

RUIZ CASTANEDA, M. Preparation and Properties of Purified Rickettsial Suspensions. *J Immunology* 1948, Mar., v 58, No. 3, 283-92, 5 figs. [18 refs.]

Workers interested in the preparations of rickettsial antigen will wish to read this paper in the original text, in which the author gives details of his recent improvements in the methods of purifying and concentrating suspensions of epidemic and murine-typhus rickettsiae obtained from the lungs of mice and rats infected by the intranasal route.

The suspensions are used for agglutination, complement fixation opsonic, and allergic skin tests as well as for the preparation of vaccines.

The author remains convinced that his bivalent lung vaccine is preferable to the commonly used monovalent vaccines because murine rickettsiae can easily be obtained in large quantities from rat lungs, whereas epidemic rickettsiae have to be prepared from mouse lungs, and also because in Mexico, and perhaps in other countries, murine typhus is not only endemic but also epidemic when transmitted from man to man by lice.

The bivalent vaccine when given in three doses of 11 into drifia our in Mexico but the author believes that a course of five doses given at weekly intervals will afford complete protection.

Photomicrographs are reproduced to show the morphological appearance of the rickettsiae as seen in stained smears and it is stated that the murine rickettsiae occur as small rods of uniform size, whereas the epidemic are pleomorphic and of variable size but most of them are larger than the murine.

WALKER, R H. Fatal Anaphylaxis following Typhus Vaccine Injection. *J. Am. M. A. Bull.* 1948, May April, v 48 No. 3, 213-5 10 (

FOX, J P & PETERSON O L. The Antirickettsial Effect of Thionine Dyes. II. On the Mode of Action of the Thionine Dyes in combating Experimental Infections of Mice with *Rickettsia orientalis* and *Rickettsia mooseri*. *J Immunology* 1948, Mar v 58, No. 3, 299-321 [38 refs.]

In this paper the authors describe the results of studies in continuation of those already reviewed in this *Bulletin* 1947 v 44 813]

Toindime blue and methylene blue in suitable doses were found effective in combating rickettsial infection in Swiss mice. The strains tested were a sharp strain of *Rickettsia orientalis* and two strains of *R. mooseri*.

A distinct, but less pronounced, effect was caused by six other related dyes azure C azure A brilliant cresyl blue azure B thionin blue and methylene blue. A number of other related compounds were found to be ineffective.

The mechanism of the anti-rickettsial effect of the drugs has not been explained, but it is thought to be associated with the chemical structure and known properties of the compounds.

Full details are given of a large number of experiments, these, and the discussion of the mechanism of the action of the drugs, will be of special interest to workers on chemotherapy. Unfortunately the authors cannot hold out any hopes that any of the drugs tested will be useful in the treatment of human rickettsial diseases.

SAYERS, M H P & HILL, I G W. The Occurrence and Identification of the Typhus Group of Fevers in South East Asia Command (Written in 1945) *J Roy Army Med Corps* 1948, Jan, v 90, No 1, 6-22, 1 chart & 1 map [18 refs]

This paper, written in 1945, contains a useful summary of the occurrence, geographical distribution, epidemiology, special features, and laboratory findings relating to the cases of fevers of the typhus group observed in the hospitals of the South-East Asia Command during the years 1941 to 1944. Almost all the information contained in the paper has already been published in articles which have been reviewed in this *Bulletin*.

About 5,500 cases were diagnosed during the period and it can safely be assumed that more than 90 per cent of these were mite-borne. The only outbreak that can with reasonable certainty be regarded as tick-borne was a small group of 33 cases at Ranchi, Bihar, India, in 1943. In the other outbreaks there were a few scattered cases in which a predominating agglutination response of the *Proteus* OX2 type or of the combined OX2 and OX19 types suggested that the infection may have been tick-borne. There were also a few cases in which a response of the OX19 type was regarded by the author as evidence of flea-borne infection. [This type of response is regarded by American observers as occurring frequently in the tick-borne Rocky Mountain spotted fever]

HORTON, R G, KAREL, L & CHADWICK, L E. Toxicity of γ -Benzene Hexachloride in Clothing. *Science* 1948, Mar 5, 246-7

Tests conducted by the U S Department of Agriculture at Orlando, Florida, have shown that herringbone twill impregnated with 2.0 grams of γ isomer of hexachlorocyclohexane (G B H) per square foot of cloth is highly effective against mites and withstands repeated laundering better than other mite impregnates. But unusual symptoms appeared in 2 workers engaged in preparing batches of the compound for field tests, which suggested that G B H may be absorbed through the skin. In order to investigate this possibility, 40 per cent acetone solutions of the pure γ isomer, or of a mixture of hexachlorocyclohexanes containing 83 per cent γ isomer, were applied to the backs and sides of a variety of animals clipped or depilated 24 hours previously, care being taken to prevent ingestion or inhalation of the compound during the initial 72-hour period of observation. Herringbone twill cloths impregnated by spraying with, or by machine-dipping in, an acetone solution of 2 grams of γ isomer per square foot of cloth, were also applied as snugly fitting coats, the covered area of clipped skin per unit body weight corresponding approximately to that for a man in a suit. A number of rabbits and rats died within a few days, displaying symptoms typical of parenterally administered G B H. Guinea-pigs were much less sensitive than the other species. The total loss of G B H from the impregnated suits amounted to 17 per cent after one

23 per cent. after two wearings and 36 per cent. after three launderings and so wearings. Bodily motion seemed to contribute to an increased rate of absorption, presumably because small crystals flaked from the fibres and worked into the skin. The authors think it probable that γ benzene hexachloride can be used safely as an impregnate only at concentrations so low as to eliminate any advantages as an insecticide it might possess over other compounds under test.

G. R. Cameron

HUENNER, R. J., HOTTE, G. A. & ROBINSON, Eleanor B. Action of Streptomycin in Experimental Infection with Q Fever. *Pub. Health Rep. Wash.* 1948, Mar 19 v 63, No. 12 357-62.

Streptomycin has already been shown to have a strongly inhibiting effect on the organisms of epidemic typhus, endemic typhus, Rocky Mountain spotted fever and rickettsialpox [see this *Bulletin* 1948, v 45 321]. The authors have now found that the drug has a similar action on *Rickettsia burneti*.

With doses proportional to those commonly employed in human therapy the drug was found highly effective in the treatment of guinea-pigs infected with large doses of virulent *R. burneti*. The treatment, however, was started much earlier than would be possible when dealing with the disease in man.

A similar inhibiting effect was observed when the drug was injected into yolk sacs just before these were inoculated with *R. burneti*.

In both sets of experiments the action of the drug was rickettsiastatic, not rickettsiacidal.

YELLOW FEVER

VEGHEM RODRIGUEZ, A. Control del *Aedes aegypti* en Chile. [Control of *Aedes aegypti* in Chile.] *Bol. Oficina Sanitaria Panamericana*. 1947 Oct., 26, No. 10 832-3. English summary.

Although *Aedes aegypti* exists along the coast of Chile from Arica to Coquimbo there have been no outbreaks of yellow fever in that country for 35 years. Arica is an important land sea and air port and international crossroads in the extreme north of the country and although the port itself is free from *Aedes*, the Department of Arica, with vast frontiers, adjoins endemic areas in neighbouring countries. The Chilean Government adheres strictly to existing conventions and has signed one recently with the Government of Peru and Bolivia regarding a campaign against the yellow fever vector.

The foci of *Aedes* in Arica at some 5 kilometres from the airport also sea-going vessels anchor 1 kilometre from the port for health inspection. Despite this, additional measures were introduced in a campaign started in Arica in 1946. These included revision of the census of wells, anti-larval measures, the use of DDT in dwellings and on water deposits, inspection of traffic, aerosol bomb fumigation of aircraft, health education and biological campaign, consisting of placing *Gambusia affinis* in every water pool or reservoir.

An *Aedes* index of 40 per cent in 1945 was reduced to zero in January 1946, and is still maintained there. An outbreak of yellow fever in the Santa Cruz Department of Bolivia caused these measures to be intensified. In 1946 166 aircraft were inspected and insecticides applied. Vaccination against yellow fever is not provided in Chile, there is no necropsy service and no confirmed foci of jungle yellow fever have appeared in the country up to now.

DENGUE AND ALLIED FEVERS

ROSS, S G Dengue Fever at Fanning Island (Central Pacific) *Med J Australia* 1948, Jan 17, v 1, No 3, 63-6, 2 figs

Among 46 cases of dengue seen at Fanning Island in 1946 and 1947 there were 32 that were "afebrile" or "nearly afebrile". Nearly all of these modified attacks occurred in persons who had already suffered from the disease during their stay on the island or before their arrival. Similar attacks occurred in two volunteers who allowed themselves to be bitten by experimentally infected *Aedes aegypti* mosquitoes. One of the volunteers had a typical attack of dengue five years previously, the other had a severe attack six months earlier.

The modified attacks rarely lasted more than four days, the temperature was usually normal, a rash was seen in five of the patients on the face, wrists or ankles, frequent and painful micturition was a prominent symptom, the pains and blood changes were of the types commonly observed in typical cases of dengue.

From a study of the cases the author concludes that there is support for "the theory of tolerance to the virus of dengue after reinfections", but he thinks it probable that "a few different immunological strains of dengue virus are present at Fanning Island" because he saw a few cases of the modified type among persons who had had no previous attacks. *John W D Magaw*

MARIOTTI, M Febbre da pappataci e febbre delle macerie con eritema persistente facciale quale utile segno di diagnosi postuma [Sandfly Fever with Persistent Facial Erythema as a Useful Diagnostic Sign] *Acta Med Italica* 1948, Jan. v 3 Supp No 1 26-35 English summary (7 lines)

PLAGUE

GIRARD, G Sur un point de terminologie l'expression *peste sylvatique* ou *sylvatique* est fondamentalement erronée ["Sylvatic Plague" an Error] *Bull Soc Path Exot* 1948, v 41, Nos 1/2, 15-16

A fundamental error in terminology which has gained 20 years start may simply have to be accepted. Girard, however, calls attention to the derivation of the word "sylvatic" from the Spanish *selva* and the Latin *silva*, a wood, and contends rightly that the rodent vectors of this form of plague inhabit steppes and not forests. Sylvatic plague rodents are the tarbagan, the spermophil, the squirrel, the gerbil, the multimammate mouse, and the cui—they dwell in the steppes of Asia or Russia, the plains of America, the deserts of Africa, and the veld of South Africa. Similar objections were taken to the word "Sylvatic" by Adolfo Pozzo [this *Bulletin*, 1946, v 43, 880] who suggested the description "rural" plague as the antithesis to "port" or "urban" plague. That may apply to South America, but would not apply universally. In fact, Girard maintains that all plague, at least in North Africa, in French West Africa, in Madagascar, in the Netherlands Indies or in British India, whether it be plague of town, village, or jungle hamlet, is murine, and that the only reservoir is the domestic rat. It suffices then to distinguish plague rodents simply as wild and domestic. *W F Harvey*

HERRIVAUX, A. & TOUMANOFF C. *Epidémiologie de la peste à Saigon-Cholon* (1943). L'étude de la faune pulicidienne des rats dans ses rapports avec la transmission de la peste. [Rat Fleas and Plague in Saigon.] *Bull. Soc. Path. Exot.* 1948, v 41 Nos. 1/2, 47-59 [12 refs.]

An epidemic of 42 cases of plague in 1943 with 5 sporadic cases in 1944 was the subject of study by the authors. Their tabulated results are presented for rats, mice and muskrats respectively. A hint of caution is thrown out as to deductions from these figures for the *X. cheopis* index of the epidemic was only 2.63 and never reached the annual mean figure of 5 per rat, which is said to represent an epidemic danger point. The authors found that on all the animals *X. cheopis* was the predominant flea, there was no correlation between the index and the course of the epidemic. *X. cheopis* was the predominant flea on the mice and *Leptopylla musculi* was never seen on this animal. *Cimexcephalus* fleas of dogs and cats seemed to have a seasonal prevalence opposite to that of *X. cheopis*. *X. astus* played a feeble, if any part as a plague vector.

SHARIF M. Nutritional Requirements of Flea Larvae, and their bearing on the Specific Distribution and Host Preferences of the Three Indian Species of *Xenopsylla* (Siphonaptera). *Parasitology* 1948, Feb., v 38, No. 4 253-63. [41 refs.]

Much experimentation by the author has shown that a mixture of dried blood and yeast provides an ideal food for flea larvae and this has been used as control diet for comparison with other possible diets. The results obtained have been checked statistically for significance and relate in particular to the 3 species of *Xenopsylla* found in India: *cheopis brasiliensis* and *astus*. The irregular distribution, especially of *cheopis* and *astus* has been the subject of much discussion, as also has the question of the possibility of survival of fleas and their larvae in grain in course of shipment to distant places. In this research attention was concentrated on the suitability of various foods for the flea larvae as judged by the duration of larval life up to the beginning of pupation or cocoon formation. Ordinarily flea larvae feed on decaying organic matter containing microorganisms and it has been determined that their principal requirements are proteins and vitamins. The test and control diets used were (a) blood alone (b) highly milled wheat flour devoid of bran, (c) blood and wheat flour and (d) blood and yeast. One general fact emerged from these experiments, that the deep brown colour and sclerotization of adult fleas obtained from larvae of all three species depended on the presence of haemoglobin in the diets, which again, it is suggested, is dependent on the iron content of the haemoglobin.

The results of the tests were that pure blood was inadequate as a diet for flea larvae probably owing to deficiency in vitamin. Growth of larvae on pure wheat flour was erratic and probably necessitated the presence of microorganisms. Thus, the presence of microorganisms, whether fungi or yeast is evidently one of great importance and was exemplified by the fact that a mixture of blood and wheat flour although quickening larval development was not a satisfactory diet. The conclusion is drawn that larval diets containing blood or wheat proteins and vitamins of the B group are essential for the successful rearing of these rat fleas. From the tests also certain conclusions could be reasonably drawn as to the distribution and host preferences of adult fleas thus *X. astus* will flourish in the burrows of *Talpa indica* and *Bandicota musshardi*, because these provide the larvae with rich food. On the other hand, *X. cheopis* and *X. brasiliensis* larvae will subsist and develop on much simpler diet and prosper readily in a burrow of the domestic rat.

even where the nutritive value of the larval food is very low " Temperature tolerance is a factor which is lowest for *X brasiliensis* and this leaves *X cheopis* as the flea with a probably wider distribution because of the simpler larval requirements than either of the other two As *X brasiliensis* and *X cheopis* larvae grow better than *X asha* on flour alone, " this possibly enables them to survive transport in grain even without rats, to places far from their original home " W F Harvey

QUAN, S F, FOSTER, L E, LARSON, A & MEYER, K F **Streptomycin in Experimental Plague** *Proc Soc Exper Biol & Med* 1947, Dec, v 66, No 3, 528-32, 4 figs

Streptomycin, if available, may replace sulphadiazine in the treatment of plague, or possibly, be used along with a sulphonamide and with serum Details are given of (1) *Results obtained in vitro* These showed that streptomycin was bactericidal and appeared to be more active on virulent strains (2) *Effect on mice and guinea-pigs infected subcutaneously* The treatment was by subcutaneous injection, was post-infectious (48 hours), and was more effective than sulphonamide treatment (3) *Effect on septicaemic plague in mice* Cure was obtained in 80 to 90 per cent of non-bubonic septicaemic plague infections, of a type resembling the clinical form of human septicaemic plague, if the treatment was begun early and the doses large (4) *Effect on pneumonic plague in mice* " As might be expected 200 to 400 μ g of streptomycin hydrochloride every 6 hours, effectively cure 90 to 95 per cent of the infections " Smaller doses and delay in treatment reduce the chance of cure (5) *Suggested schedule of treatment in human plague* Streptomycin, the most effective therapeutic agent yet discovered " for the treatment of bubonic, septicaemic and pneumonic experimental plague infections in mice and guinea-pigs ", should be given in human plague at the earliest diagnosis, in daily doses subcutaneously of 2 gm in bubonic plague, 4 to 6 gm in septicaemic and pneumonic plague The intervals of injection should be 4-6 hours for the first two days, after which the dose may be reduced It is recommended, however, that to prevent recurrence one gramme should be continued daily for at least 8 days, unless it is more convenient to substitute sulphonamide therapy at this stage The simultaneous administration of potent antiplague serum may be required in profound toxæmia W F Harvey

POLLOCK, J S M **Plague controlled in Haifa by the Use of DDT alone** *Trans Roy Soc Trop Med & Hyg* 1948, Mar, v 41, No 5, 647-56, 2 figs

The efficient control of human plague would seem to be in sight, and the author hopes that " the world has seen its last widespread plague epidemic " Immediate measures are designed to break the rat-flea-man chain by attacking the flea with DDT Treatment of patients proceeds as usual, reliance being placed on sulphadiazine and streptomycin Long term measures may be taken up, as and when possible Experience in previous outbreaks was of thousands of pounds spent on anti-plague measures and yet without influence on the course of the epidemic

Haifa is probably a fairly typical Turkish town of olden times A main paved sewer runs from end to end of the old city and from May till November never runs full Its sides are shelved and give both ideal runways and breeding places for the sewer rat Dwellings are crowded, each has a dark damp basement, which is, under present circumstances, itself a human habitation and has direct branch communication with the main sewer The

port of Haifa on the other hand is quite modern, but is closely linked with the old city. It is a busy inward and outward port and is provided with extensive grain and food stores.

The first case of bubonic plague in the outbreak under review was admitted on 28th June 1947 and proved fatal. Full-scale plague precautions were immediately taken in five sectors of the city in each of which a DDT team laid down 5 per cent. residual spray using the Four Oaks knapsack sprayer. Impediments were cleared by labourers. A sixth team was mobile for the spraying of "house and work place of each suspected case and their surroundings. It was possible with this organization to lay down 500 gallons of DDT spray daily. At the same time, great publicity was given to the need for residual spray in houses, and 10 per cent. dusting powder for bodily use. Centres were set up at which power-driven compressor blowers were used for dusting purposes and these centres became very popular with the specially important lower class, Arab population. As many as 30 000 persons were dusted in the first 10 days.

The last plague case seems to have occurred on 19th July. "In all nineteen bacteriologically proved cases of plague were treated in the Government Hospital, Haifa" all of them were bubonic. Six other cases were clinically bubonic, but not proven bacteriologically. Only one case the first proved fatal. The circumstantial evidence produced in this outbreak would indicate that by using DDT as the first line of attack together with a modified cordon sanitaire rat extermination, while important, may take secondary place and should be planned on a long term continuous preventative basis."

NICHOLSON H. P. & GAINES T. B. A Comparison of the Effectiveness of 5 and 10 per cent. DDT Dusts for the Control of Rat Fleas. *Pub Health Rep Wash.* 1948, Jan. 30 v. 63 No. 5 129-33, 4 figs.

Field studies were made in July 1948 at Columbia, S.C. U.S.A. to determine the value of dust containing 5 per cent. DDT and 95 per cent. pyrophyllite for the control of rat fleas, and to compare the results with those obtained in 1945 in Savannah, Ga. where 10 per cent. DDT dust was used.

The rat infested establishments were shops, cafés, warehouses, etc. in both places, and similar premises were used as checks. The insecticide was applied to the rat burrows by dust gun and to the runs by shaker. Photographs of this equipment are given. All rats trapped (except six *Rattus uticus* in the Savannah test) were *Rattus norvegicus*. The fleas were predominantly *Xenopsylla cheopis* the following species being rare both in treated and untreated establishments: *Xenopsylla fasciatus*, *Leptopsylla segnis*, *Echimopsylla gallinacea* and *Cimex cephalotes*.

The rats were trapped before treatment 6 to 8 days after treatment, then at intervals of 6 weeks for about three months. Because of the scarcity of other species, comparison of results is based on the effects on *X. cheopis*.

The rat flea populations were almost completely eliminated within a week after application of both the 5 per cent. and the 10 per cent. DDT dusts in every type of treated premises. There was no significant degree of recovery after three months and no significant difference in the results of the two formulations. The maximum duration of effective control could not be determined.

CHOLERA

UNDERWOOD, E A *The History of Cholera in Great Britain* *Proc Roy Soc Med* 1948, Mar, v 41, No 3, 165-73 (Sect Epidem & State Med 1-9), 1 fig [37 refs]

The history of cholera in Great Britain is one of little more than 100 years. True cholera was known as Asiatic and on its arrival had to be distinguished from the simple indigenous "cholera nostras". The first death from true cholera in Britain occurred in Sunderland on October 20, 1831. Cholera then spread epidemically, affecting the north of England and south and mid-Scotland, later it spread to England generally. At first cholera was regarded as a visitation of Divine Providence and as a catastrophe in the lives of the poor. The opinion seems to have changed somewhat when cholera became a pestilence sparing "neither age nor sex nor station". Much discussion raged on whether cholera could be called contagious and Snow's essay of 1849 was entitled "On the Mode of Communication of Cholera", it was followed by his further publications. He asserted his belief that the excretions of the sick contained the contaminating material and by multiplication in the small intestine gave rise to the disease. He also promulgated the doctrine of water-borne cholera, which received strong support from the episode of the Broad Street Pump in St James's Parish in London. The Board of Guardians ordered removal of the pump handle and the incidence of new cases in this area ceased almost at once. The epidemics of cholera in Great Britain caused "the deaths in England and Wales alone of 21,800 persons in 1832 53,292 in 1848-49 20,099 in 1853-54 and 14 378 in 1866". The 1832 epidemic and subsequent visitations have close connexions with the establishment of social reforms formation of the great Prudential Insurance Company and the building up of "quarantine and other measures which have kept this island almost inviolate for eighty years".

W F Harvey

TAYLOR, J *Epidemiology of Cholera* [Summary] *Proc Roy Soc Med* 1948, Mar, v 41, No 3, 174-6 (Sect Epidem & State Med 10-12)

Most of the points made in this important communication have already been summarized [see this *Bulletin* 1948 v 45, 175]. It may be well to add that the actual mode of introduction into Egypt of the first infection has not been established. "So far we have no definite information on how infection was introduced to Egypt at a time when the disease had not been reported as occurring in any other country west of India. Air or sea carriage from the East must be presumed".

W F Harvey

WHITE, P B *Bacteriological and Immunological Aspects of Cholera* [Summary] *Proc Roy Soc Med* 1948, Mar v 41, No 3, 176-7 (Sect Epidem & State Med 12-13)

A remarkable interest attaches to this communication because of its author and his connexion with the application of "the receptor analysis methods of Weil and Felix" to the conception of a true cholera vibrio. Very great advances were made, but there is still disputation on the subject. One of the current dicta is now abandoned. Bruce White finds indisputable evidence of the transmutability of Ogawa and El Tor vibrios to Inaba vibrios by "focusing the serous influence" on the type-specific O antigen with the use of strictly monospecific antisera. Thus he establishes the fact that "the types are not separate species or subspecies but phases of a single species" and describes this find-

also as "something like the specific and non-specific phases of the Salmonella. At the same time he expresses agreement with the view reached by Sir John Taylor on the collected results from an attempt to classify 311 vibrio strains, inagglutinable with O group 1 serum, that "with one possible exception, no case for the cholorigenic activity of any of these could be made out"

W. F. Harvey

GOMAR, M. A. Isolation of the Cholera Vibrio. *J. Trop. Med. & Hyg.* 1948 Mar. v. 51 No. 3 59-60 1 fig.

Two labour-saving methods for speedy isolation of the cholera vibrio in times of epidemic are here described. The first requires a 25 ml. conical flask filled with alkaline peptone water to the bottom of its neck thus giving a concentration within a small surface area of the strongly aerobic vibrio growing rapidly from the faeces inoculum. Growth is taken from this surface to a semi-sloped mannito Andrade agar to which has been added about 1 ml. peptone water thus providing a composite stab slope and peptone water culture. The second improved method, especially useful for examination of convalescents or carriers omits the preliminary enrichment and selection. The faecal matter or vomit, is inoculated into a wide tube 3 cm. in diameter containing 0.5 per cent. agar dissolved in alkaline peptone water in which a piece of glass tubing about 6 cm. in length and 3 mm. in diameter is immersed. The medium rises in the small tube and is to be covered by about 5 mm. height of alkaline peptone water. After inoculation of the large tube, its surface is covered with a thin layer of sterile liquid paraffin to seal it. In this method advantage is obviously taken "of the active motility and strongly aerobic character of the cholera vibrios which" leads to their concentration in the only part exposed to the air in the small immersed glass tube. The further examination is according to routine.

W. F. Harvey

GALLUT, J. Sur le mécanisme de la réaction du choléra-rouge. [Mechanism of the Cholera-red Reaction.] *A. n. Inst. Pasteur* 1948, Jan. v. 74 No. 1 27-39 5 figs. [11 refs.]

Those who would follow the argument presented should read Gallut on the utilization of glucose by the cholera vibrio [this *Bulletin* 1947 v. 44 660 and 1948, v. 45 177] as well as the work of Sax and his fellow workers (*ibid.* 1947 v. 44 209). The essence of the cholera red reaction is the ability of the cholera vibrio to transform nitrates and to produce indole from peptone. As the production of nitrites is practically independent of the method of culture the variation in positiveness of the colour reaction must be based on the conditions for development of indole, except that the colour quality is conditioned by the nitrite:indole ratio—orange for a value greater than 1 (red "solferino") for a value between 1 and 2, and violet if greater than 2, when the concentration of indole is more than 50 mgm. per litre. Apart from these facts and the fact that in a glucose medium the production of indole and therefore the cholera red reaction is independent of the oxidation-reduction potential, we have to consider especially the part played by glucose in the reaction. In the total absence of glucose it is a simple reaction: if glucose is present the reaction demands its complete combustion, as distinct from fermentation products, activity fatal to the vibrio before it can be manifest. Moreover there are certain limits of concentration of the glucose within which the reaction can take place and which provide the time-table conditions for its optimum appearance. Other factors which come into play are those of anaerobiosis, aerobiosis and aeration of the medium.

The Chemotherapy of Cholera

Sulphaguanidine has been used in the treatment of cholera, but has not been conspicuously successful even where it was combined with hypertonic saline. Now the prospect appears of direct therapy with a new sulphonamide compound, which differs from the older compounds in not being a substitution derivative of sulphanilamide but a condensation formed by the molecular combination of two compounds, sulphathiazole and formaldehyde. Laboratory investigation showed that this preparation was markedly bactericidal and inhibitory. Animal experiments were carried out on mice and these involved both pre-infectional and post-infectional therapy, of 40 mgm daily for 4 days in the latter case, with groups of 20 animals each for intraperitoneal and subcutaneous routes. The test intraperitoneal dose of virulent Inaba vibrios did not exceed 2 MLD so as not to kill animals by toxic effect and the protection reached 100 per cent. Oral therapy in the experimental animals was not so effective and saved only 20 per cent, while the control group mortality was 100 per cent. The drug, owing to its low solubility in water, was given as a 20 per cent suspension in 2 per cent gum arabic. Absorption and excretion are both slow so that it is easy to maintain a long and effective blood concentration.

In the field so far as first trials have gone, results are very satisfactory with the extraordinary saving of 82 patients out of 85 treated. Moreover "the patients were treated in their homes without the benefit of nursing and general medical care and no complementary treatment was resorted to". One advantage of treatment at home was, of course, the saving of an exhausting journey to hospital. The authors rightly stress that control of an epidemic of cholera by 7 days of therapy, producing complete freedom of the stools from infective vibrios is an event of major importance. That applies also to the use of the drug prophylactically in carriers who, if treated before panic or pilgrimage dispersal occurs may be rendered harmless. The average amount given over 7 days was 16 gm for a child, 23 gm for a woman and 25-30 gm for a man.

In one important respect the field trials differed from the animal experimentation in that administration was more successful by the oral route than by subcutaneous inoculation. No appreciable toxic effects were observed even with a 50 gm dose if cholera vomiting was extreme the drug was given.

The cyclical development of the spirochaeta in lice was observed in seven experiments and in the last four the same strain was transmitted through four successive batches of lice. The lice were infective the day after their infective meal, but were negative on the 3rd, 4th and 6th days, but positive on the 5th and 7th. No actual spirochaetes were seen in these lice and proof of infection depended on animal experiments.

The authors are of the opinion that the infections produced by lice during the first 10 days after an infective feed are caused by the organism in an invisible phase.

The cycle of *S. duboni* in the louse seems to differ from that of the East African strain of *S. recurrentis* as the latter shows a more definite negative phase. [See this *Bulletin*, 1948, v 45 86.] In both, however the negative cycle is terminated by the appearance of slender cork-screw-shaped metacyclic forms about the 15th day.

The course of the louse-transmitted *S. duboni* infection in monkeys, mice and a rat and a hedgehog is given in tabular form. The results show that in pathogenicity it resembles the tick transmitted infection. Moreover, the results of cross-immunity tests clearly indicated that the infection in animals after the fourth transmission by means of lice, was serologically identical with the ordinary strain of *S. duboni* and distinct from *S. recurrentis*.

E H Ellis

NAIR, L. A. Sterile Splenic Abscess after Relapsing Fever. *Lancet*. 1948, Apr 10 555-8, 3 figs.

This paper is based on 7 cases admitted to the Kasr El-Nay Hospital, Cairo between April and June 1948, during the decline of the epidemic of relapsing fever which attacked Upper Egypt during the winter of 1945-1946. Splenic abscess in relapsing fever is a rarity. EL RAMLY [this *Bulletin*, 1948, v 45 185] finding only 23 instances in 3 000 consecutive cases treated during the epidemic of 1945-1946. Of 139 fatal cases, splenic infections were found at necropsy, in 28, of which 16 showed abscess formation.

In the present series, 4 were males and 3 females, and all gave a history of relapsing fever. The 3 females had had neosarsphenamine (2 or 3 injections, dose not stated).

The condition began with sudden pain, usually described as severe, under the left costal margin. In some cases referred to the left shoulder or epigastrium and usually subsiding without treatment.

In all cases there was an interval, after the pain had subsided, before abdominal swelling was noticed, and it was only after this mass had become very large that medical advice was sought. One patient sought aid for cough and pain in the chest, at a time when no mass was palpable in the abdomen. This developed in three weeks after the onset of pain. Where no chest complications were present there was no change in general health pulse or temperature but where the chest was involved the patient had fever dyspnoea raised pulse and toxæmia.

The liver was enlarged and tender in most cases. The splenic enlargement differed from the usual type in that (1) it did not move on respiration, but was firmly fixed (2) its borders were rounded and a notch was felt in one case only (3) it was cystic and was tender in the early stages (4) in one case there was shifting dullness in the pleen (5) Traube's area was dull even in cases with no left pleural effusion. The size of the pleen varied the smallest reaching a finger breadth above the umbilicus, the largest nearly to the right iliac fossa.

Pleural effusion was present in 2 cases when they were first seen, the effusion in both being sterile and requiring repeated aspirations. Some of the early cases were misdiagnosed as retroperitoneal sarcoma, renal tumour, etc. One patient was first seen still complaining of the initial pain without enlargement of the spleen and the case was mistaken for pleurisy with effusion. Radiography always showed a raised immobile left dome of the diaphragm.

No malaria or relapsing fever parasites were found and, apart from one case of secondary infection, there was no rise in the polymorphonuclear leucocytes, even with a high leucocyte count. The Wassermann reaction was positive in the 4 cases where it was tested.

In the earlier cases, penicillin or sulphadiazine or both were given before operation, with no apparent good result. Splenectomy was not attempted in any cases owing to the dense adhesions and fixation of the mass, the abscess being drained through a separate left subcostal incision.

Unless secondary infection is present, penicillin and sulphonamides are not required and in early cases simple drainage results in cure. Post-operative complications were (1) left pneumonia followed by empyema, and (2) secondary infection from the operation sinus.

The spleen was transformed into a large sac with a dense fibrous wall, a rim of spleen tissue being found at the lower pole which was free. The abscess cavity was usually single and lined with shreddy necrotic tissue. The liver was enlarged and in some cases very congested.

The pus was odourless and usually a dull greenish-yellow colour, viscid and slimy. It was sterile in 6 cases in 1 case *Staph aureus* was found. Early lesions showed much necrosis and aseptic suppuration compatible with the formation of a sterile abscess but not hitherto described in relation to relapsing fever. [This complication must be a very rare one]

ORTUZAR R, Pozo, S & ROSATI, S. Sodoku, septicemia a estreptococo moniliforme y fiebre de Haver Hill [Sodoku, Streptococcus moniliformis Septicaemia and Haverhill Fever] Rev Med Chile 1947 Dec v 75, No 12, 774-S, 2 figs

This is another attempt at solving the problem of rat-bite fevers, Haverhill fever and that produced by *Streptobacillus moniliformis*. There is no little obscurity regarding these conditions. Sodoku is known to be due to *Spirillum minus* (*Spirochaeta morsus muris*), Haverhill fever is regarded as a form of rat-bite fever but the spirillum is not found and *Streptobacillus moniliformis* can be cultivated. On the other hand cases of Haverhill fever are recorded in which rats or rat-bites cannot be incriminated [see this Bulletin, 1942, v 39, 693]. A full table giving the distinctive characters of sodoku and rat-bite Haverhill fever is reproduced in this Bulletin 1944, v 41, 943. The present authors see three distinct diseases in this group namely, sodoku, a septicemia due to *Streptobacillus moniliformis* inoculated by the bite of a rat, and Haverhill fever due to the same organism but conveyed by contaminated food and not by rats and they give in the accompanying table the distinguishing features [Since Haverhill fever has been shown in some cases at least to be due to rat-bite it seems incorrect to restrict the name as the authors have done to the syndrome unassociated with such a history. Would it not be better for the present at all events to discard the name Haverhill fever and divide the three under two main headings fever due to *Spirillum minus* and diseases due to infection by *Streptobacillus moniliformis* and subdivide the latter into that associated with the bite of a rat and that associated with contaminated food?]

| | Sodoku | Septicæmia due to <i>Streptobacillus moniliformis</i> | Haverhill Fever |
|---|-----------------------------|---|---------------------------------------|
| 1. Causal agent | <i>Spirillum minus</i> | <i>Streptobacillus moniliformis</i> | <i>Streptobacillus moniliformis</i> |
| 2. Mode of infection | Bite (rat) | Bite (rat) | Contaminated food |
| 3. Incubation | 1-3 weeks | 1-3 days | 3-8 days |
| 4. Local changes and regional lymphadenitis | Marked | Slighter | Absent |
| 5. Septicæmia | Moderate | Marked | Dominant |
| 6. Cutaneous erythema | Marked; macular and papular | Marked papular morbilliform | Morbilliform, petechial, polymorphous |
| 7. Joint involvement | Absent | Commonly present | Usual features |
| 8. Splenomegaly | Absent | Commonly present | Usual features |
| 9. General adenopathy | Absent | Occasional | Frequent |
| 10. Cyclic course | Absent | Frequent | Frequent |
| 11. Haemoculture | Negative | Positive | Positive |
| 12. Effect of Arsenic | Good | Little or none | Little or none |
| 13. Effect of Penicillin | Slight | Good | Good |

Notes of 5 cases are given: one of sodoku, one of *S. moniliformis* septicæmia from rat-bite and resembling sodoku, one designated glandular fever (Haverhill fever) with no history of rat-bite, one of epidemic arthritic erythema (Haverhill fever) with general adenitis, and one of *S. moniliformis* septicæmia with valvular endocarditis associated with this organism and ending fatally.

H. Harold Scott

NOUÏ M. Contribution à l'étude du sodoku et recherche sur l'action du sérum antispirelle. (Contribution to the Study of Rat-Bite Fever and Research on the Action of Anti-spirillum Serum.) Bull. Soc. Path. Exot. 1947 v. 40 No. 11/12, 430-33

Immune serum was prepared by inoculating sheep over a period of 14 months with blood and emulsions of liver and spleen taken from guinea-pigs infected with *Spirillum minus*. Spirilla were never found on macroscopical examination of the sheep's blood but the organism could be demonstrated by subinoculation of guinea-pigs or mice.

The lytic action of the serum in vitro was examined in 3 tests.

(1) 1.0 ml. amounts of a 1:5 dilution of blood from guinea-pig Lea dy infected with *S. m.* were mixed with undiluted serum in quantities from 9 to 2 ml. The mixtures were control containing 9 ml. of normal saline were inoculated for 2 hours at 35°C. Doses of 1 ml. were inoculated into guinea-pigs, 3 being used for each dilution.

(2) 2 ml. of a similar 1:5 blood suspension were mixed with 1.0 to 0.1 ml. serum, incubated 2 hours at 35°C. and made up to 4.0 ml. with normal saline. Again 3 guinea-pigs were inoculated from each dilution.

The control animals died in every case, but not a single guineapig which received the mixtures containing serum, showing that the antiserum had completely inhibited the spirillum

(3) The infected material in this case consisted of a mixture of blood and emulsion of liver and spleen. Volumes from 9.9 to 80 ml were mixed with antiserum in amounts to give a final volume of 10 ml (0.1-2 ml serum), and incubated as before. In this test, 2 guineapigs were inoculated from each dilution. The controls died, but the results of the serum mixtures were indefinite. Most of the animals became infected after long incubation periods, showing that the serum had only retarded the development of disease.

Serum from normal sheep and from syphilitic patients had no inhibitory action. The effect is therefore specific to anti-spirillum serum.

Prophylaxis was tried by injecting serum [dose not given] into guineapigs 2-4 days before infection. No protection was obtained. Attempted treatment of infected animals with serum was also ineffective.

LEPROSY

CHAUSSINAND, R. Sexe et lèpre [Sex and Leprosy] *Internat J Leprosy*
Cleveland, Ohio 1947 Oct-Dec, v 15, No 4, 406-16

This is a careful survey of the question, based on extensive data and it brings out some new points. The author found 75.5 per cent of 1,002 cases to be in males, in accordance with general experience. Age curves show little difference in the first decade and after the 45th year, and the greatest preponderance of males between the ages of 15-20, this is attributed to a much larger number of males who contract the disease outside their families owing to great promiscuity in the course of their work and to greater susceptibility attributable to endocrine differences. In another table, 4-5 years are allowed for the incubation period and the probable dates of contamination in the two sexes are shown for each five-yearly period. The curves of these data show that up to the age of 15 there was a slightly higher percentage of infections among female children, after which the percentages fall in both sexes but more rapidly in females who are less exposed to extrafamilial infections. The curve of females also shows slight rises between 25-29 and 40-44, that is, during the period of most active gestations and at the commencement of the menopause, which somewhat increase the susceptibility of females, and are indications of the influence of endocrines. The benign nerve form is rather more frequent among females, and another table and curves of the age, sex and type on admission show a preponderance of the nerve form in males up to the age of 9, and a very large one in females of 40 and upwards. On the other hand, the lepromatous form is much more prevalent among females up to 29 and in males over 39 years of age. Thus, in general, the evolution is more serious in males, and females show more resistance except at an early age and during the period of gestation. All the data are based on experience in Cochinchina.

HARBITZ, F. Lepraforskning i Norge gjennom hundre år [Leprosy in Norway during a Century] *Nordisk Med* 1948, Apr 2, v 38, No 14, 677-9

The English summary appended to the paper is as follows —
"This centenary address gives a survey of Norwegian contributions to leprology the great descriptive paper by DANIELSSON & BOECK published in

Ross, C M Some Differences in the Leprosy of the Gambia and Nigeria
Leprosy Review 1948, Jan, v 19, No 1, 12-14

This note is based on a survey of 17,000 Gambia people in three areas extending up the river, with much lower humidity in the inland areas. The social conditions and diet are poor, meat is rarely eaten, and vitamin B is deficient. Eye lesions and rickets are common. Clinical and bacteriological examinations were made in all suspected cases. The percentages of different types were: lepromatous 13.5 per cent, tuberculoid 71.0 per cent, and unclassified 15.5 per cent. As compared with experience in Nigeria, lepromatous nodules were larger and they were present on the mucous membranes. In tuberculoid cases, a greater proportion showed erythematous reacting conditions. In a young female, small tuberculoid macules half encircling her body had the distribution of herpes zoster. The lepra bacilli in slides were relatively more numerous in each of the three types than in Nigeria, and scantily positive slides were astoundingly common in tuberculoid cases as compared with the negative results found in the Owerri Province of South Nigeria, and 19 to 40 per cent of tuberculoid cases were thus scantily positive. Unclassified cases showed 85 per cent to be positive. Nerve involvement was also more frequent. The highest incidence was found in the vitamin deficient upper river area, and the lowest at the mouth of the river where there were better conditions as regards vitamins and social aspects.

Ryrie, G V Regional Differences in Leprosy. Leprosy among Chinese in Malaya. *Leprosy Review* 1948, Jan, v 19, No 1, 4-11. 1 graph

This is an interesting comparison between the types of leprosy seen among Chinese, Malays and Indians in Malaya based on a large experience.

The disease is most virulent among Chinese and least so among Indians, three-fourths of the cases among the latter being of mild tuberculoid disease with a tendency to self-healing, but among the Chinese only one-third are of the tuberculoid type. The climate of Malaya is of the hot humid type, in which leprosy flourishes. On the other hand, a higher standard of living than in India tends to hinder the spread of the disease. The age incidence is important. Among the Chinese early macules are commonly found in children of 5 to 15 years of age, most of which tend to clear up, but in about one fourth tuberculoid lesions develop and may go on to the lepromatous condition, especially if the onset of the tuberculoid stage occurs early. When a reliable history is obtained in Chinese, in nearly every lepromatous case a tuberculoid stage was first observed, commonly in the age group 16-40. In a smaller number of persons of over 40 years of age, the proportion of tuberculoid cases is very much higher, but the tendency to become lepromatous is very much less. Major tuberculoid cases are more liable than minor to become lepromatous, but nerve thickening in tuberculoid leprosy is less evident in Chinese than in Indians, and it is rare in children and in those over 40. In view of the foregoing peculiarity of the evolution of leprosy in tuberculoid cases in Chinese subjects, active treatment is necessary, in order to prevent them becoming lepromatous. For this purpose, intradermal injections are of little value and they tend to obscure any evolutionary changes. Hydnicarpus oil or esters (deep subcutaneous injections) should therefore be pushed to the limit of tolerance in doses of 1 cc per 10 pounds body weight twice weekly, or 30 cc per week, for a patient of 150 lbs as a minimum, and increased by at least fifty per cent in acute or reacting cases, when improvement may be expected within three months. Some years' experience of this intensive treatment as compared with weekly injections of 1-5 cc has shown much more marked improvement and much less incidence of

used together with healthy control subjects and the reactions to intradermal injections of the antigens were noted after 24 and 48 hours and at the third week for early and late appearances, illustrations of which are recorded. The results showed that the three oily suspensions of *Mycob. leprae* antigens produced intense local reaction in 24 to 48 hours in all cases of leprosy including the lepromatous type, but they were most intense in tuberculoid cases. As early reactions were as constant, although less severe, with oily suspensions of typhoid bacilli they are not considered to be specific. Control tests showed that the early reactions are not due to the oily vehicles used, so the intense reaction in tuberculoid cases indicates that action of *Mycob. leprae* is increased in an oily suspension. The authors therefore think that the oily vehicle maintains contact of the bacilli with the dermis at the site of injection. Late reactions in tuberculoid cases were intense with hard infiltration and sometimes ulceration. In lepromatous cases a non-inflammatory nodule or plaque persisted, well localized and never ulcerating. In persons considered non-lepromatous, infiltrated nodules or plaques with at times central areas of necrosis, were seen but less intense than in tuberculoid forms. A further interesting observation was that in several lepromatous cases intradermal injection of the oily suspensions of *Mycob. leprae* were followed after three to five months by positive reactions to standard lepromin, but this change in the allergic state lasted for only a short time, after which lepromin again gave negative results. This temporary sensitization to lepromin is being further studied.

DHARMENDRA. The Lepromin Test—A Review. *Leprosy Review* 1947 Oct. v 18, No 4 92-126 1 coloured pl. [99 refs.]

This is in itself a comprehensive summary of the literature of the subject with full references and quotations of the most important data on its various aspects from the first intracutaneous injections of lepra bacilli by MITSUDA in 1916. The advances made by HAYASHI in 1933 the suggestion of FERNANDEZ that the early and late reactions may be due to different antigens, and the explanation furnished by Dharmendra himself that protein constituents account for both reactions (the delayed one being, due to slow breaking up of the injected whole dead lepra bacilli in the tissues) are well brought out. Findings are quoted which indicate that the test was of considerable value in classification of cases, and in prognosis but little in diagnosis and treatment. Among matters regarding which there is still much difference of opinion may be mentioned the significance of occasional reactions in healthy subjects and in contacts of infected cases claims that repeated tests may increase the resisting powers of children to infection stronger reactions in summer than in winter variations in reactions in different skin areas and the effect of debilitating conditions in reducing reactions all of these require further investigation. A careful discussion on the nature of the reaction leads the author to the conclusion that a positive lepromin reaction is an allergic phenomenon. Another use of the test is to determine if a given acid-fast bacillus is that of lepra or some other form for infection if the latter give positive reactions in lepromatous as well as in other types of leprosy which *Mycob. leprae* does not. This useful publication should be kept at hand for reference by all using the lepromin test the results of which are illustrated by a coloured plate.]

IGNACIO J. L. & TIONG J. O. Further Observations on the Mitsuda (Lepromin) Reaction in Leprous Children. *Monthly Bul. Bure. of Health Manila* 1947 Feb-Mar v 23 No. 2, 83-101

This paper confirms the work of LARA (this Bulletin 1940) 37 632 on a tendency of young children to react more strongly to lepromin with increasing

age and with repeated tests Three groups of children, amounting to a total of 216, were tested with lepromin, the results are tabulated and discussed. The greater proportion of strong reactors in those tested several times, compared with those injected with lepromin only once or twice, is noteworthy. Direct relationship between repeated testing and clinical improvement or subsidence of leprotic lesions indicates a favourable influence of the lepromin in children and may indicate that lepromin has some immunizing value, especially when the subjects are of about the same age, but further work is required to establish such an effect. Further, in 31.5 per cent of first injections the original lesions had apparently already healed which indicates increased natural resistance after childhood, as is believed to be the case with tuberculous children. Strong reactions probably indicate a relatively high degree of resistance with a better prognosis, but the relationship is not constant. Children showing consistently weak reactions also have a poor prognosis, but they form a small minority of the cases. These observations confirm the prognostic value of lepromin reactions. L Rogers

NOLASCO, J O The Potency of Stored Lepromin *Monthly Bull Bureau of Health* Manila 1947, Feb-Mar, v 23, No 2, 103-14

Quotations from medical literature show very varying opinions on the keeping powers of lepromin so this paper is timely. The lepromin used in the present investigation was prepared by the technique of Hayashi, and was proved by microscopical examination to contain numerous well-preserved lepra bacilli, some in globi but as the number may vary much in different specimens, this method of preparation is capable of improvement. In the first series of tests before the Japanese invasion of the Philippines eight lepromins, which had been stored for 1 to 41 months in a refrigerator, were all injected in the forearms of twenty patients and weekly observations were made up to the 28th day, these are discussed in detail. Except for some minor variations in the reactions following the use of particular samples, all gave normal reactions with ultimate suppuration of the nodules at the sites of injection. In a second series, seven specimens kept throughout the war, with only very occasional refrigeration for a few hours, up to periods of 49 to 96 months, together with a control only 14 days old were injected simultaneously in another group of twenty patients. Microscopical examinations showed undiminished numbers of lepra bacilli in all the specimens, and once more the reactions were typical. The author therefore concludes that lepromin prepared by the Hayashi-Mitsuda method keeps its properties undiminished for very long periods without any necessity for its being preserved in a refrigerator. This book is reviewed on p 658

WOLCOTT R R Erythema Nodosum in Leprosy *Internat J Leprosy* Cleveland, Ohio 1947, Oct-Dec v 15, No 4, 380-88, 4 figs (1 on pl)

The author states that erythema nodosum occurring in leprosy is often confused with acute lepra reactions and he gives the following points of differentiation between the two conditions. Erythema nodosum differs from the acute lepra reaction in that its onset is less abrupt the numerous evanescent discrete red nodules rarely show lepra bacilli, fever may be absent or intermittent, and without loss of weight and strength. Moreover, the lesions of erythema nodosum are painful on pressure, show vascular changes and are common under

sulphone treatment, during which lepra reactions are rare. Very numerous nodules may appear within a few hours, and fresh lesions may occur when the first have subsided. Oedema of the corium with swollen connective tissue fibres are found microscopically and the appearances indicate an antigen-antibody immune reaction. There is a close relationship to treatment, for only 7 per cent. occurred before treatment was begun, but they were more frequent under sulphone treatment and also of shorter duration and their appearance is considered to be a definite indication of the resistance of the host. Intramuscular injections of Fousidin in 3-5 cc. doses produced general improvement after a few days, and this allowed antileprous treatment to be continued without interruption in nearly all the cases especially when sulphones were being used.

ROGERS, L. Combined Chaulmoograte and Sulphone Treatment of Leprosy and Tuberculosis. *Lancet*. 1948, Apr 3 315-17 [14 refs.]

LANCET 1948, Apr 3 524 Chemotherapy of Leprosy

Oral administration of chaulmoogra oil in the past was so nauseating that few leprous patients could be induced to persevere with it. Great advance therefore was made when its active constituent sodium hydnocarpate Alepol which was given by injection, was substituted. The author in 1916 demonstrated that subcutaneous injection of alepol led to the breaking up of the bacilli sometimes with softening of nodules, and, later that, when intravenously injected, it produced more rapid destruction of the bacilli and more rapid improvement in the lesions. But intravenous injections in allanced cases might result in long-continued fever and debility although the clearing up of lesions might be remarkable. The author therefore proposed that injections should be given intramuscularly, for some weeks and, when progress began to slow down, the intravenous route should be used for a few doses. The mode of action of the drug was found to be by its fat-splitting property and by breaking down the protective fatty envelope of the bacilli and rendering them vulnerable.

In recent years, sulphone preparations have been used in treatment of leprosy and favourably reported upon, especially Promin by PAGET *et al.* [this Bulletin 1947 v. 44 591] in the Carville leprosarium, and Promisole and Diasone by the same workers and by MUIR (*ibid.* 328 327). The latter drugs have the advantage of oral administration, whereas the first must be injected. These drugs act by destroying the bacilli entering the blood-stream, so that fresh lesions by blood transmission are prevented.

The author has shown thus that the actions of chaulmoogra and these sulphones are complementary the former destroying the bacilli in large numbers in the leprous lesions with the risk of surviving organisms being disseminated by the blood, whereas the latter destroy them when they reach the circulation. In order to ensure the presence of the bactericidal drug in the blood before pushing the chaulmoogrates to the point of softening of the lesions and dispersion of organisms, it is recommended, says the author that several weeks' treatment with one of the sulphones should precede the larger doses of chaulmoogra.

Analogies between *Myc. leprae* and *Myc. tuberculosis* have naturally led to the suggestion of using sodium hydnocarpate and morrhuate in tuberculosis, and success has followed the use of colloidal copper morrhuate *Gadum*, in this disease the author suggests that trial should be made of this in combination with sulphones or with streptomycin in tuberculosis on the same principles as in leprosy."

A leading article on this subject points out that the actual evidence of chaulmoogra preparations being bacteriolytic is not strong and that their effect may be due to counter-irritation and the stimulation of a tissue response. The article also refers to untoward and possibly dangerous side-effects of treatment with sulphones, such as gastro-intestinal disturbance, haemolytic anaemia, haematuria and even agranulocytosis. It is suggested, further, that *p*-aminosalicylic acid, which seems to have some specific action on acid-fast bacilli, has low toxicity and has been tried in tuberculosis, might, when it is more readily available, be given a trial in leprosy.

FAGET, G H & ERICKSON, P T **Chemotherapy of Leprosy** *J Amer Med Ass* 1948 Feb 14, v 136, No 7, 451-6, 6 figs [Refs in footnotes] *H Harold Scott*

This paper records the latest observations on the sulphone treatment of leprosy. This group of drugs has now been under trial in lepromatous cases at the Carville Settlement, U S A, for six years, almost entirely with better results than any former treatment. Promin on account of its toxicity has to be given intravenously in doses gradually increased from 1 to 5 gm daily for two weeks at a time, with one week's interval at the end of each fortnight. Diasone is given orally, beginning with 0.3 gm in a capsule or as a tablet daily, and increased if well tolerated to two or three such doses daily, with periods of two weeks' rest after every two months' treatment. Promizole is given orally 0.5 to 1 gm three times daily and gradually increased to the optimum dose of 6 to 8 gm a day. No renal damage was found from any of them under the carefully controlled conditions of medication, but careful watch must be kept for anaemia or leucopenia, which may require temporary cessation of the treatment and the use of iron or liver therapy.

Most of the patients treated had advanced lepromatous disease notes and illustrations before and after treatment of three cases show striking improvement. Progress is seldom evident in less than six months and is very slow, but steady with very few relapses and is in proportion to the duration of treatment. Promin and diasone give very similar results. Of the patients treated, 25 per cent show improvement after six months, 60 per cent after one year, 75 per cent after two years and almost 100 per cent after three years' treatment. It is shown by slow shrinking and absorption of nodules until only a pigmented scar may remain, ulcers develop healthy granulations and heal and there may be some regrowth of hair. Mucous lesions respond better than cutaneous lesions. The frequency and severity of reactions are reduced. *Lepra bacilli* in the lesions gradually become less numerous and after four years they disappear in over 50 per cent. Those entering the blood stream are eliminated and the development of fresh lesions is prevented. The histological changes in lesions are of an atrophic nature. The proportion of cases in which the disease is arrested under prolonged promin and diasone treatment is 83 per cent in 1-2 years, increasing to 21 to 29 per cent after three to six years. Antibiotics have also been tried in leprosy, but penicillin is only of use in secondary infections of ulcers. Streptomycin has given encouraging results, but they are not as yet conclusively demonstrated and require further tests. In a discussion on the above paper, H M Johnson of Honolulu reported encouraging results in Hawaii from the use of promin and diasone. *L Rogers*

JOHANSEN F A & ERICKSON, P T **Promizole Treatment of Leprosy** (A Progress Report) *Internat J Leprosy* Cleveland, Ohio 1947, Oct - Dec v 15 No 4 378-9

This note records a trial lasting two and a half years of Promizole in leprosy at the Carville Leprosarium U S A. It was found to be slightly less toxic than

the other sulphones but does not appear to have any other advantages. It is given orally in doses six to eight times as great as those of promin or thasone and becomes distasteful and unpalatable. It also produces a harmless cherry red colour of the urine. It is synthesized with difficulty and is expensive. Treatment was started on 25 patients, who have fallen to 15 of whom 7 have been under treatment for 2½ years, but two of these are now using other preparations. Two of the patients have become negative bacteriologically and clinical improvement continues to take place. Of 5 patients treated for only one year all are still bacteriologically positive. Three of the patients have died of intercurrent diseases. In view of these drawbacks it is not proposed to continue the trials after the present supplies of promizole are exhausted.

L. Rogers

DE MESQUITA A. P. Seabra's Photo-Oxidase Test in Leprosy *Med. Times*. New York. 1948, Feb., v 78 No. 2, 56-60 73 4 figs.

This paper describes a new prognostic test of a technical nature. Seabra has studied oxidases and worked out an index for them in the leucocytes, which varies with barometric pressure and a photo-oxidase test for measuring them. The erythrocyte oxidase falls in tuberculous subjects and this is due to "Factor P" secreted by tubercle bacilli inactivating the hase produced by the lymphocytes. Seabra also found a similar drop in erythrocyte oxidase in a few cases of leprosy. This test has now been applied in 100 leprosy cases, with the result that the lowest readings are found in the more serious cases with the worst prognosis, mainly lepromatous disease in which it is below the normal limit of 40. In nerve cases classed by the South American nomenclature as "uncharacteristic" and tuberculoid on the other hand, the readings are usually above 40. Thus among 67 lepromatous cases, Seabra's photo-oxidase tests showed low figures in 53 (79 per cent.) Of 14 cases without low readings, 6 have greatly improved and 8 have become free of cutaneous signs. The nerve types revealed normal readings over 40 in 25 of 33 cases (75-76 per cent.) and several of the exceptions were not doing well. A table and illustration show the readings in the 100 cases. For technical details, the original should be consulted.

- 1 KREIS, H A Eine systematische Bemerkung zur Arbeit H Vogel und W Minning Ueber die Einwirkung von Brechweinstein, Fuadin und Emetin auf Bilharzia japonica und deren Eier im Kaninchenversuch [Comment on the Paper by Vogel and Minning on "The Action in Rabbits of Tartar Emetic, Fouadin and Emetine on *Schistosoma japonicum* and its Eggs"] *Acta Tropica* Basle 1947, v 4, No 3, 259-60
- 11 ——— Bilharzia oder Schistosoma ? Ergänzende Mitteilung zur Bemerkung H A Kreis in *Acta Tropica* Vol. 4, 259-260, 1947 [*Bilharzia* or *Schistosoma* ? Further Communication] *Ibid* 1948, v 5, No 1, 87-8

1 VOGEL and MINNING's paper was abstracted in this *Bulletin* [1948, v 45, 196] and the author of this comment does not criticize the work which he says is of much interest, but he objects to the name of the trematode. He traces historically the changes in the naming of this worm. Bilharz describing it in 1852 called it *Distomum haematobium*. Six years later, Weinland stated that it did not belong to this genus *Distomum* and put it under a new genus *Schistosoma*, and *Schistosoma haematobium* (Bilharz, 1852) became *S. haematobium* Weinland, 1858. But in the same year, Diesing gave it the generic name of *Gynaecophorus* and in 1859 Cobbold, in honour of its discoverer, called it *Bilharzia* and the same year Moquin-Tandon called the new genus *Thecosoma*. The author argues that as Weinland was the first to show that it did not belong to the genus *Distomum*, according to the laws of nomenclature its correct name is *Schistosoma*. VOGEL and MINNING, however, called the helminth they were dealing with *Bilharzia japonica* on the ground that Meckel used the term *Bilharzia* in 1856, or two years before Weinland created the genus *Schistosoma*. LEUCKART in his work on *Die Parasiten des Menschen* calls the urinary schistosome "*Bilharzia* Cobbold, 1859" which is certainly wrong if Meckel had called it so three years before. So far, all seems plain sailing, but prolonged search has failed to find where Meckel called it *Bilharzia*, and the works of Lutz, of Faust, of Worth, Martin, Hunter and others say nothing about Meckel. Therefore, until proof is obtained that Meckel *did* make the genus *Bilharzia* in 1856, the name *Schistosoma* Weinland, 1858 must hold good.

11 In his supplementary note Kreis dwells on the fact that in the account of SENN's booklet on Theodor Bilharz, Professor Leiper speaks of a posthumous work "Mikrogeologie" by Meckel von Hemsbach, published in 1856, in which the generic name *Bilharzia* is used. Meckel as the originator of the name *Bilharzia* is also mentioned in a book on *Famous Tropical Physicians* by G. OLPP published in Munich in 1932. In Professor Leiper's words "Those who regretted the displacement of the generic name *Bilharzia* Cobbold, 1859 by *Schistosoma* Weinland, 1858 under the Law of Priority will rejoice in the restoration of *Bilharzia* Meckel, 1856 under the same Law" [See this *Bulletin*, 1932, v 29, 168]. In spite of, or in comment on, this, E. W. PRICE (*J. Parasitology*, 1933-4, v 20, 111) wrote "but in this case priority is of little moment in view of the fact that in 1922 *Schistosoma* was placed on the list of official names under Opinion 77 of the International Commission on Zoological Nomenclature". To end the dilemma Dr. Kreis in 1938 asked the Commission for a decision and he received a reply from the President saying that he would bring the request to the notice of the members, he suggested that in the meantime as *Bilharzia* could obviously claim priority, this name should be used and provisionally *Schistosoma* should be inserted in brackets. Dr. Kreis says that he repeated his request in 1947, but, so far as he knows, no decision has yet been made. He adds naively, "When the decision is reached, it will be authoritative".

The present author with BLAIR treated seven patients with acriflavine in Salisbury Southern Rhodesia all suffered from *S. haematobium* infections and three had *S. mansoni* as well. The patients were adolescent school children and all were passing viable eggs. They were given the dose quoted by Fisher namely a total of 0.01 gm. per kgm. body weight in five equal daily doses of 2 per cent. acriflavine. No evidence of toxicity was noted.

At the end of treatment one patient with *S. haematobium* had ceased to pass viable eggs and remained negative for the further period of two months follow up. One month after treatment a patient who had *S. mansoni* was negative but showed eggs again after 2 months.

It is pointed out that most of Fisher's cases had become negative immediately after treatment and that, unlike the present instance his cases comprised solely intestinal schistosomiasis.

In the present author's small series of cases of vesical schistosomiasis, the effect of acriflavine was found to be almost negligible.

H. J. O'D. Burke-Gaffney

SCHUBERT M. Conditions for Drug Testing in Experimental Schistosomiasis *mansoni* in Mice. *Amer J Trop Med.* 1948, Jan. 23, No. 1 11-26 + figs. [17 refs.]

An investigation is described to find the best method for testing drugs on experimental schistosomiasis. A number of points are involved (1) The species of schistosome and its intermediate host. *S. mansoni* and *Australobius glabratus* were convenient and satisfactory. *S. haematobium* would develop well in mice but it was difficult to obtain any large number of cercariae from *Bulinus truncatus*. *S. japonicum* was not available. (2) The animal host chosen was the mouse. Hamsters develop infections more readily but are less easy to use for screening drugs. Rabbits are convenient if large numbers of adult worms are required. Rats are not very susceptible to infection, and are unsatisfactory. (3) The mice were infected by intraperitoneal injection of a standard number of cercariae. This was more convenient and uniform than immersing them in water containing cercariae. (4) The optimum number of cercariae per mouse was 100-150 when this number is injected intraperitoneally about 9 per cent develop into adult worms and 80 per cent of the mice are infected. Higher doses of cercariae kill too many of the mice. (5) Even with a standard dose of cercariae the number of worms which develop in the mice varies considerably. In groups of 15 mice there may be 5 or 20 worms in individual mice. (6) The infection in the mice becomes mature and eggs are passed, during the sixth or seventh week after infection. Treatment was therefore begun during the eighth week. There was no evidence of spontaneous cure of the mice during the first 38 weeks. (7) The drug was given daily for two weeks usually by intraperitoneal injection. If the drug was insoluble it was injected as a suspension or given in the diet. (8) The criterion of cure. Even after treatment with Fouadin or sodium antimony tartrate few if the mice become completely free from worms. Accordingly the effect may be judged by the location of the worms (antimonials drive them from the mesenteric mass into the liver) and by the percentage of worms paired (diminished by antimonials). The presence or absence of viable eggs in the faeces was found to be very variable even in untreated mice. (9) During the first two weeks after treatment worms which have been driven into the liver but not killed may recover and reascend the mesenteric mass and begin to lay eggs again. Accordingly the mice should be held for two weeks after treatment and then killed and the number and location of the worms should be compared with those of control untreated mice. Usual 10-15 mice are used in group. The

author seems to have had more difficulty in demonstrating the helminthocidal action of active drugs than KIKUTH and GÖNNERT did in Germany, the latter workers have used a similar technique since 1936 and judged the response according to the passage of eggs and the presence or absence of living worms at autopsy 4 weeks after treatment]

SCHUBERT, M **Screening of Drugs in Experimental Schistosomiasis mansoni in Mice** *Amer J Trop Med* 1948, Jan, v 28, No 1, 137-56

By means of the methods described above, over 400 compounds were tested, the names of these being given in lists According to their therapeutic effects, the drugs may be divided into four categories —

- (1) Drugs which cured most of the mice, *viz* antimony tri(2 naphthylethyl mercaptide), antimony tri(n-dodecyl-mercaptide), and n-butyl 3,4 antimonyl gallate
- (2) Drugs which killed some of the worms, *viz* Fouadin, antimony trithioglycollamide, antimonyl 2 mercaptothiazoline, antimony tri (2 mercaptoimiazogluconate, emetine, miracil.
- (3) Drugs which had only a slight action, *viz* sodium antimony tartrate and 32 other compounds
- (4) Drugs with no action

It should be noted that the pentavalent antimonials, neostibosan and neostam, both showed considerable activity and they probably deserve further clinical trials in the treatment of schistosomiasis Antimony compounds soluble in oil also seemed worth further clinical investigation Miracil was found to have considerable action when given in the maximum tolerated dose by injection or by mouth and it is said to deserve further investigation, however it was not so effective in the author's animals as it was in those of KIKUTH and GÖNNERT [This paper contains numerous data of great interest to those concerned in the search for new active compounds and should be consulted in the original]

SCHUBERT M **Effect of Drugs during Earliest Stages of Experimental Schistosomiasis mansoni in Mice** *Amer J Trop Med* 1948, Jan, v 28, No 1, 157-62

Mice were infected with *S. mansoni* by the technique described above On the first five days after intraperitoneal injection of the cercariae they were treated with daily doses of drug by intraperitoneal injection, or the drug was given in the food The purpose was to prevent the development of the infection The mice were killed and examined after eight weeks Eighty drugs were tested in this way Seven showed significant protective action, *viz* antimony tri(2 naphthyl ethyl mercaptide), Fouadin, antimony tri (n-dodecyl mercaptide) neostam, neostibosan, urea stibamine and sodium antimony tartrate (in order of decreasing activity) The doses used were approximately the maximum tolerated ones Miracil showed very little activity

KUNTZ, R E, STIREWALT, M A & BUCHHEIT, J R **Method for testing Ointments and Fabrics to determine their Effectiveness as Barriers to Schistosome Cercariae** *Amer J Trop Med* 1947, Nov v 27, No 6, 691-7, 4 figs [11 refs]

Control of schistosomiasis in war may be attempted by destruction of the snail hosts (only moderately successful hitherto), temporary elimination of

cercariae by cercaricidal substances or by protection of the skin by the use of uniforms made from protective fabric or the use of repellents or barrier substances. In tests on animals estimation of the penetrating power of cercariae by keeping the animals for 15-40 days and then dissecting them and counting the parasites which have developed is cumbersome and the authors have devised a shorter test which is probably sufficiently accurate. It is based on the observed fact that cercariae of *Schistosomium douglasi* and *Schistosoma mansoni* penetrate hamsters and white mice with equal facility and are affected to about the same extent by barrier substances. These animals show skin reactions when the cercariae have penetrated but certain white rabbits about 6 months old constantly show much more prominent reactions to cercariae of *S. douglasi* which render assessment of invasion much easier. It can be assumed, therefore, that the skin reaction due to *S. douglasi* is a reasonably accurate index of the invasive powers of equal numbers of cercariae of *S. mansoni* under the same conditions (but the authors do not prove that what is true of hamsters and mice is necessarily true of rabbits).

The authors describe a rubber belt containing four test chambers of glass tubing 1 inch in diameter which is applied to the skin of the belly of the rabbit. Into these chambers about 25 cercariae are introduced and left for 1 hour (with clothing barriers 50 cercariae are left for 1 hour) and the numbers of inflamed spots caused are counted every 4-8 hours for 2 days. The barrier ointments are placed on the skin before the cercariae are applied, but the fabrics are placed 1-3 mm. from the skin and the intervening space is filled with water. The cercariae are placed outside the fabrics.

For details of these procedures the original must be consulted. No results of actual tests are given. According to the list of references most of the work done on fabrics and barrier substances has been recorded in official reports.

Charles H. Welch

PERIGAN, T. P. The Endemicity of *Schistosomiasis japonica* in Sorogon, Southeastern Luzon. *J. Philippine Med. Ass.* 1949 Jan., v. 24 No. 1 19-27 1 fig. & 1 map on pl.

The known endemic foci of *S. japonicum* infection in the Philippine Islands are Eastern Leyte, Samar, Surigao and Agusan especially around Lake Mainit and Mindoro near Lake Naujan. Another focus has recently been found in Western Lanao [see this *Bullet.* 1947 v. 44 832]. The author has now confirmed a newly discovered endemic area in Sorogon, Luzon. He had observed a few patients in the Philippine General Hospital, who came from Sorogon, and he therefore made a survey in that area finding 25 infected persons most of whom had never left the district. A few of these persons were unaware of any serious illness, but in 16 the liver was enlarged, and distension of the superficial abdominal veins was found in 7. No less than 6 had had epileptiform attacks, but this should not be regarded as indicating the proportion so affected, since these patients were examined for schistosomiasis because they gave this history.

Search for snails revealed *Oncomelania quadrasi* in three streams out of many investigated. None of the snails was infected but there is little doubt that this species well known as the intermediate host elsewhere is responsible for spread here.

In addition to schistosomiasis the author found other infections in 113 of 114 persons examined including paragonimiasis and balantidiasis in one boy.

JAHNES, W G & HODGES, E P. An Improved Method of sedimenting *Schistosoma japonicum* and other Helminth Ova. *J Parasitology* 1947, Dec, v 33, No 6, 483-6 [15 refs]

The authors tested a number of chemicals and reagents in a search for the most effective method of sedimenting eggs of *S japonicum*. A control method of evaluating the tests consisted in the use of 0.5 per cent of glycerine in tap water. Of all the materials employed, 10 per cent ethyl alcohol (sp gr 0.986) gave the best results, with the highest egg counts and no distortion. The procedure is as follows: 5 gm of stool are emulsified, strained through four layers of moistened gauze and allowed to sediment for 1 hour, 45 minutes and 30 minutes successively, decanting at each time interval and replacing with fresh solution. After the final sedimentation, 0.15 cc are taken from the top and bottom of the residual sediment, respectively, and examined.

HUNTER, G W, HODGES, E P, JAHNES, W G, DIAMOND, L S & INGALLS, J W, Jr. Studies on Schistosomiasis II. Summary of Further Studies on Methods of Recovering Eggs of *S japonicum* from Stools. *Bull U S Army Med Dept* 1948, Feb, v 8, No 2, 128-31, 2 figs [Refs in foot-notes]

Previous studies described evaluation of the various laboratory methods available for diagnosing *S japonicum* infection [this *Bulletin*, 1947, v 44, 440]. The present paper makes further comparisons and indicates that two new methods have shown themselves to be superior to all others in current use.

In the comparisons, qualitative and semi-quantitative estimations were made of 10 techniques, with the use of stools of dogs infected with *S japonicum*, naturally infected human stools and those of monkeys infected with *S mansoni*. The techniques were (1) direct smear, (2) sedimentation, (3) hydrochloric acid, Triton NE, ether centrifugation, (4) hydrochloric acid, sodium sulphate, (5) sodium sulphate Triton NE, ether centrifugation, (6) sodium sulphate, ether, xylol, (7) funnel centrifugation, (8) AMS I method, (9) centrifugal sedimentation, now reported as the AMS III method, (10) a modification of the AMS II method, (10) a modification of the AMS I technique.

The AMS I technique was a modification of the Telemann hydrochloric acid and ether method as used by WELLER and DAMMIN [this *Bulletin*, 1947, v 44, 98] except that the hydrochloric acid was mixed with equal parts of sodium sulphate. The AMS II method modified the AMS I technique by using 2 gm of stool, by washing with water centrifugation before the HCl, sodium sulphate Triton NE, ether centrifugation technique and by swabbing out the tube before decanting the final residue on to a slide. The AMS III method substitutes washing 3 times with the HCl and sodium sulphate mixture instead of water before treatment by the HCl, sodium sulphate, Triton NE ether technique. The last named method is described in detail in the text. It requires less than 15 minutes. A total of 37 qualitative and 15 semi-quantitative comparisons were made. In every case, the AMS II and III proved to be the most satisfactory. The results are shown in two figures, which demonstrate strikingly the superiority of these two methods and particularly of the AMS III. Not only are more eggs revealed, but the slides are washed cleaner and are therefore comparatively easy to read.

It is added that the AMS III technique also appears to be efficacious for the detection of other helminths, and has the advantage of detecting *S japonicum* eggs whether they are immature, mature or degenerate. It can also be used satisfactorily in examining stools of those who have already been treated.

HUNT W. E., ABRAHAMSON W. & WEAVER, T. A. Jr. Cerebral Schistosomiasis. Report of a Case simulating Cerebral Neoplasm. *J Amer Med. Ass.* 1948 Mar 8, v 136 No. 10 688-9 8 figs. [Refs. in footnotes.]

A white labourer aged 35 years, served with the army in Leyte where he bathed in proscribed fresh water streams. In the United States in September 1946 he began to suffer from transient loss of motor and sensory function on the left side of the body and right sided headache on one occasion he lost consciousness during an attack. Changes in his personality were noticed by his wife. In November 1946 a diagnosis of brain tumour was made after electroencephalographic and ventriculographic examinations. At operation, scattered white milium nodules were seen on the right cerebral convolutions. In the posterior portion of the inferior frontal gyrus there was a nodule about 5 mm. in diameter which was removed. On section schistosome ova, surrounded by lymphocytes and eosinophiles, were found lying in an area of connective tissue proliferation containing Langhans-type giant cells. Repeated stool examinations sigmoidoscopic scrapings and urine examinations failed to yield schistosome ova, but the patient was put on a course of antimony potassium tartrate. He made a good recovery but there was some residual weakness of the left arm and he suffered an abortive sensory seizure some five months after the operation and treatment. [See also this *Bulletin* 1947 v 44 916.]

CARROLL, D. & HUNNIXEN, V. V. Studies on Schistosomiasis japonica in the Philippine Islands. 3. A Clinical Study of 72 Cases treated with Tartar Emetic. *Bull Johns Hopkins Hosp* 1948 Mar v 82, No. 3 346-72

The treatment of *S. japonicum* infections on Leyte in 1944-45 with Fouadin has already been reported (this *Bulletin* 1947 v 44 834). The present report deals with 72 patients treated with tartar emetic, 32 of whom were followed into their seventh month of illness.

All cases were primary infections in hitherto unexposed American soldiers. The incubation period averaged 50 days for 68 cases. Five cases were classified as severe, 31 as moderately severe, 32 as mild and 4 as asymptomatic.

In treatment 1.89 gm. of tartar emetic was used. The stock solution was 0.4 gm. of the drug per 100 cc. 1.5 per cent. dextrose in normal saline; the solution was not heated and was used within 3 hours of being mixed.

The solution was given in graded doses intravenously every other day for 18 doses, namely: 1st dose 0.020 gm. of tartar emetic (5 cc. of solution); 2nd, 0.040 gm.; 3rd, 0.060 gm.; 4th, 0.080 gm.; and, after the fourth dose 0.120 gm. (30 cc. of solution) for all further doses.

In the first four doses the solution was diluted with the dextrose-saline to make 30 cc. of liquid injected. Injection was made into the antecubital vein over a period of about 10 minutes. Early minor reactions were cough, nausea and vomiting, while in some patients stiffness of the joints developed later as more of the drug was given. A chart indicates that there were many minor reactions; also in four cases tartar emetic had to be discontinued owing to purpura, substernal pain, vascular collapse and cough with diarrhoea and vomiting, respectively. One month after the course of tartar emetic was completed 32 patients were retreated with 40 cc. of Fouadin owing to the presence of degenerated eggs in their stools. The Fouadin was given intramuscularly in doses of 5 cc. daily for 8 days.

All patients were discharged after 1 to 4 months; few of them felt completely well, although they carried on light duty. Of 31 patients weighed 7 months later 35 per cent. had lost weight. There was no striking clinical

improvement with the institution of tartar emetic therapy After the third month, glandular enlargement was no longer appreciable, and the spleen and liver tended to remain palpable in only a minority of the patients These features are shown in a chart

Tabulated figures for leucocyte and eosinophile counts are given as time passed, these counts approached normal Sedimentation rates of 29 patients in the 7th month were normal

Two of the patients showed mature *S japonicum* eggs in the 16th week after tartar emetic treatment and 2 in the 17th week Three of these 4 had been retreated with Fouadin

In 8 of 32 patients in the 7th month, sigmoidoscopy showed nodules in the rectum or sigmoid Only one of these had a positive stool and 4 had been retreated with Fouadin

The authors found no significant difference between the cases which recurred and those which did not in regard to the original leucocytosis and eosinophilia or for these values at the end of seven months Retreatment with Fouadin was not effective in preventing recurrences None of the asymptomatic cases recurred. The impression was gained that patients having tartar emetic had fewer recurrences than a comparable group treated with Fouadin alone [*loc cit*]

KHOO, F Y & CHIANG, H-S Hookworm Disease showing Abnormal Roentgenologic Small Intestine Changes Three Case Reports *Chinese Med J Shanghai* 1947, Sept-Oct, v 65, Nos 9/10, 349-56, 4 figs on 2 pls

Since MACKIE [*Med Clin North America*, 1933, v 17, 165] drew attention to the radiological changes in the small intestine in non-tropical sprue, considerable attention has been paid to the radiological picture in tropical gastrointestinal disorders and malnutritional states

Golden has divided these changes into two main classes,

- (i) Changes in motility, hyper- and hypo-motility and -tonicity, abnormal segmentation, scattering effect, and gas and fluid levels, and
- (ii) Changes in the mucous membrane —exaggeration or obliteration of the mucosal folds

These changes are not pathognomonic of any particular condition, but occur in many nutritional disorders whether these are primary, or secondary to disease of the intestinal tract Worm infections are included amongst the latter

In 1943, KRAUSE and CRILLY [this *Bulletin*, 1944, v 41, 139], reporting on 97 cases of *Necator americanus* infection in white adult males, found in varying

species development is slow and somewhat irregular compared with what takes place in *C. salicis* and *C. dimidiata* in W. Africa.

Three hundred individuals of *C. distinctipennis* and *C. longicornis* were dissected after feeding on *Los*-infected blood. Growth was slow and 18-20 days were required before the embryo reached the stage of full larval development. Out of 600 caught in the wild state 0.66 per cent. were infected with *L. los*. Both these species of *Chrysops* were furtive in habits, lacked the voracity of other biting flies, and so were seldom observed to bite man willingly—they fed mostly on cattle.

This study suggested that some other vector must transmit *L. los*.

From two surveys of inhabitants living near breeding places of *Simulium damnosum* in areas where filarial blindness had not been observed it was found that 77 per cent. had *O. rostratus* embryos in the skin.

Antigen was prepared from avian filariae infecting wild doves and gave a positive intradermal reaction in 91 per cent. of cases (but only 4 tests are recorded, of which 2 were negative) harbouring either *L. los* or *L. perstans*.

GIGLIOLI G. The Transmission of *Wuchereria bancrofti* by *Anopheles darlingi* in the American Tropics. *Amer. J. Trop. Med.* 1948 Jan. v 28, No. 1 71-85. (13 refs.)

Previous work is reviewed on anopheline mosquitoes of the *Anisotrypanus* group, and *Aedes aegypti* as hosts of *Wuchereria bancrofti*. The present investigations were made in two coastal areas of British Guiana where *Culex fatigans*, *Anopheles darlingi* and *Aedes aegypti* are habitual house frequenters. In one locality *Culex fatigans* predominated and in the other *Anopheles darlingi*. For the study of natural infections in wild female mosquitoes captures were made in the houses at random and the mosquitoes were brought to the laboratory and dissected the same day. Experimental infections were made with laboratory-bred mosquitoes. The technique was standardized so that early stage infections of doubtful value were excluded. More than 10,000 mosquitoes were dissected. From the evidence collected in the field and confirmed by experiment, *A. darlingi* is as good as if not better than *Culex fatigans* as vector of *W. bancrofti*. Laboratory experiments proved beyond doubt that the development of *W. bancrofti* proceeds equally well in both species.

As *C. fatigans* does not fly far from its breeding places, this may account for the tendency of filarial infection to spread among the inmates of a single house. The wider flying range of *A. darlingi* presumably allows its visiting many houses, thus distributing the infection over a wider area than *C. fatigans*.

Attempts to infect *Aedes aegypti* failed entirely. The experiments are fully described and the findings tabulated.

HARNED B. H., CLINCHAM R. W., HALLIDAY J. B. L., VELEY R. E., YUDA N. N., CLARK Mary C., HINA Carolyn H., CONGER Rachel & SUMMAROW V. Studies on the Chemotherapy of Filariasis. VI. Some Pharmacodynamic Properties of 1-Diethylcarbamyl-4-Methylpiperazine Hydrochloride, Hetrazan. *J. Lab. & Clin. Med.* 1948 Feb. 33 No. 216-33 8 figs. (14 refs.)

Hetrazan is a new compound which is very promising for the treatment of human filariasis (this *Bulletin* 1948 v 45 353). It has a low toxicity and few side reactions. For mice the intraperitoneal LD₅₀ (dose causing 50 per cent. mortality) was about 250 mgm. per kgm. and the oral LD₅₀ 600 mgm. per kgm.

Single intraperitoneal injections of 100 mgm per kgm were readily tolerated by mice, rats, rabbits and dogs. Rabbits tolerated daily intraperitoneal doses of 50 mgm per kgm 5 days per week for 14 weeks, rats tolerated a similar schedule of 100 mgm per kgm, and dogs treated orally tolerated 25 mgm per kgm twice daily for 2 months.

The compound was not irritating, produced no local anaesthesia, no effect upon the eye, no effect on the isolated uterus or intestine, and no effect on the blood sugar. It was mildly diuretic and analgesic. Intravenous doses of 2 to 25 mgm per kgm in unanaesthetized dogs stimulated the respiration. The heart and blood pressure were not affected by rapid intravenous injections of 0.5 mgm per kgm, but larger intravenous doses in unanaesthetized dogs produced a transient deviation from the normal. No chemical method for estimation of the drug is known at present, but experimental evidence was obtained that it is rapidly excreted by the kidney, the rate per hour in rats and mice being approximately one-third of the intraperitoneal LD₅₀. WILLIAMS, R W. Studies on the Life Cycle of *Litomosoides carini*, Filariid Parasite of the Cotton Rat, *Sigmodon hispidus litoralis*. *J Parasitology* 1948, Feb., v 34 No 1 24-43 8 figs on 2 pls [49 refs]

ANTUNES, M L. Notas sobre a incidência da enterobiose [The Incidence of Infestation by *Enterobius vermicularis*]. *Hospital* Rio de Janeiro 1947, Dec, v 32, No 6, 971-9, 2 figs & 1 graph [12 refs]

The author examined 100 children attending his clinic in São Paulo, which is connected with the Legião Brasileira da Assistência, to determine the prevalence of infestation by *Enterobius vermicularis*. The total is, of course, far too small to give a true indication of the prevalence. He chose, as the most reliable method, the NIH swab with Cellophane. The ages of the children ranged from 2 to 10 years. Whereas only one was detected by direct faecal examination, 30 were found at the first swab examination and of 43 examined twice 12 more were detected. Thirty, or less than one in three, of the children had any itching of the anus, and 17 of these were infested and in more than half the positive cases pruritus was not a symptom. As regards age, of 23 between 2 and 3 years 6 were positive, of 31 between 3 and 5 years 14 were positive, of 30 between 5 and 7 years 15, from 7-9 years 5 out of 11, and 3 out of 5 of those up to 10 years of age. Forty-three were boys and 17 of them were positive, of 57 girls 25 were positive or 42 in all among the 100 examined. The next commonest infestation was by *Ascaris lumbricoides* (36), the third by *Trichuris trichiura* (15). *Giardia intestinalis* cysts were seen in thirty. H Harold Scott

MAC KEITH R & WATSON, J M. The Diagnosis and Treatment of Threadworm Infestation. *Practitioner* 1948 Apr v 160 No 958 264-70 12 figs [13 refs]

DESCHIENS, R & LAMY, L. La thérapie chimique de l'oxyurose [The Chemotherapy of Enterobiasis]. *Liber Jubilaris J Rodham (Soc Belge Méd Trop, Brussels)* 1947, Dec, 171-94 [13 refs]

This paper consists of a review of the literature on the chemotherapy of anthelmintic drugs, especially with reference to the treatment of *Enterobius* infection. The drugs considered include santonin, oil of chenopodium, carbon tetrachloride, tetrachlorethylene, bismuth carbonate and subnitrate, the derivatives of triphenylmethane—*e.g.* alkaline fuchsin, gentian violet and

Nutritional neuropathies are considered in four groups —

1. Peripheral neuritis, including "electric feet" and cranial nerve lesions.
2. Nutritional amblyopia.
3. Spinal cord involvement.
4. Mental changes.

These manifestations are regarded as parts of a single syndrome based aetiologicaly upon a prolonged protein deficiency with a high relative carbohydrate intake and multiple vitamin deficiencies of the B group.

Factors which may be responsible for the distribution of the lesions in the central nervous system are considered in detail and the author concludes that the most important of these factors is phylogenetic seniority the younger tracts being selected first the sensory mechanism being relatively more sensitive than its motor counterpart.

HERNÁNDEZ CARRERO A. Beri-beri cardíaco. (Caso clínico) [A Case of Cardiac Beriberi.] *Salud y Beneficencia Municipal Habana, Cba.* 1947 Oct. Nov. Dec. 7 No. 4 11 19 7 figs.

GILLESPIE J. & GILLESPIE T. Liver Disease in Johannesburg: relation to Pellagra. *Lancet*. 1948, Jan. 31 169-73. [16 refs.]

In an earlier paper [this *Bulletin* 1946, v 43 364] the authors have described the pathological findings in biopsy specimens of the liver from Africans with pellagra. The changes were classified under four headings, and further subdivided according to the amount of fat present. The types were —

- i. Fatty infiltration alone.
- ii. Cytosiderosis or accumulation of an iron-containing pigment in hepatic and Kupffer cells.
- iii. Cytosiderosis, as in type ii, but with large masses of iron pigment in Kupffer cells and histiocytes of the portal tracts.
- iv. Pigment cirrhosis.

The present paper provides a background for these observations. A survey has been made of the histology of the liver in a sample of the general population, represented by an unselected series of 351 people killed by trauma. The same

| | General population | | Pellagrins |
|---------------------------------|--------------------|----------|------------|
| | Africans | European | |
| Number of cases | 281 | 80 | 17 |
| Percentage incidence of lesions | | | |
| Type | 7 | 13.3 | 4.9 |
| " ii | 45.7 | 26.8 | 23.7 |
| " iii | 26.4 | 11 | 23.7 |
| | 9.6 | | 9.7 |
| Normal | 12.6 | 4 | — |
| Other lesions | 3.0 | 4.6 | — |

classification has been used, and the results of the two investigations may be most conveniently compared in a table, derived from two tables in the authors' text

These figures show a remarkable correspondence between the pellagrins and the general population of Africans in the incidence of all except the type 1 lesions. The more chronic changes (types iii and iv) were much less common in Europeans than in Africans. There are two further significant points not brought out by this condensed table: the changes in general were less severe in Europeans than in Africans. Even slight degrees of fatty infiltration or cytosiderosis have been included in the table as type 1 or type ii lesions. Whether these slight changes should be regarded as pathological is a point upon which the authors do not commit themselves. Secondly, the lesions of all types occurred earlier—by one or two decades—in pellagrins than in the general population of Africans, and earlier in Africans than in Europeans.

The authors have extended their original conception of the way in which these pathological changes are related. "Cirrhosis can supervene at any stage in the course of cytosiderosis, and not only when the liver becomes intensely pigmented." They re-emphasize that cirrhosis is not related to long-standing fatty change. Siderosis, or the appearance of masses of pigment in Kupffer cells and histiocytes, may also develop at any stage in the evolution of cytosiderosis. "Both reactions—namely, cirrhosis and siderosis—represent distinct landmarks in the progress of the disease."

The consequences may extend beyond the liver. It is suggested that the discharge into the circulation of inert pigment of large molecular size may have important effects on other organs, analogous to those produced experimentally by the injection of synthetic polymers, and described by HUEPER (*Arch Pathology*, 1942, v 33, 267) under the name 'macromolecular syndrome'.

Since liver lesions are as common in the general population of Africans as in pellagrins, the question arises of the relationship between pellagra and cytosiderosis. The fact that pigment changes are more extensive and severe in pellagrins suggests that a relation does exist, but this cannot yet be defined with precision. The authors' view may be given in their own words: "In the general population of Africans some types of stimuli are maintaining a perverse intracellular metabolism, having as an end-result the deposition of iron pigment. This perverse metabolism can silently destroy the tissues to such an extent that the patient first becomes severely ill and presents himself at the hospital when he already has an advanced hepatic cytosiderosis with or without cirrhosis. At any stage during the progress of this pathological process, which to the untrained observer does not express itself clinically as an acute attack of pellagra may be suddenly precipitated."

J C Waterlow

DAVIES, J N P. The Essential Pathology of Kwashiorkor. *Lancet* 1948, Feb 28, 317-20 [25 refs.]

The term kwashiorkor has in recent years been extended by Trowell to include adult as well as infantile cases. Some patients may present in a chronic phase of the disease, with few specific signs except for the presence of undigested food in the stools. This paper describes the histological findings in 50 cases examined at post-mortem or by biopsy, 31 of the patients were less than 10 years old.

In the liver, the histological picture varied with the age. In children under 5 there was always some degree of fatty change. This began in the cells in the peripheral parts of the lobules, and progressed towards the centre, until

eventually every liver cell was loaded with fat. The appearance of fat was accompanied by infiltration of lymphocytes into the portal areas, and proliferation of reticular fibres into the lobules, surrounding and strangling the peripheral cells. If resolution occurred the fat disappeared first from the centro-lobular regions and last from the periphery. Great stress is laid on the predominantly peripheral distribution of the fat if fat is nodular, central or irregular some serious complication is to be suspected, and the condition is probably secondary kwashiorkor. The disappearance of fat may or may not be accompanied by clinical improvement. When all fat has disappeared, the liver is left with a patchy monolobular cirrhosis, with collections of lymphocytes at the edges of the lobules. This picture is the "hallmark of kwashiorkor" and persists throughout life. It has been found in almost every case in a series of more than 1,000 post mortems.

In older children and adults, fatty change was absent or slight except in a group of adult immigrants from the Belgian Congo. All cases presented the typical clinical picture of kwashiorkor regardless of whether the liver was fatty. Therefore the fatty change so prominent in infants, cannot be looked upon as the essential lesion in this disease. With increasing age the fibrosis became more severe the final picture was a pure monolobular cirrhosis similar to that described by VERT (this *Bull.* v 1931 v 23, 844). In most cases this seemed to be complicated in the later stages by focal necroses with regenerative hyperplasia and replacement fibrosis producing a mixed type of cirrhosis. In contrast to the findings in Johannesburg there was no excess of iron pigment and the condition never progressed to haemochromatosis. Malaria and helminthiasis were present in a few cases, but there was no evidence that these were related to the liver lesions.

Changes were also found in the kidney and pancreas. The kidneys showed hyalinization of the glomeruli, with metaplasia of the capsular epithelium and pericapsular fibrosis.

In the pancreas the earliest change was atrophy of the acinar cells, followed by hyalinization and fibrosis. In late cases the acini had disappeared over wide areas of the pancreas. Cyst formation and metaplasia of the ductal epithelium were not found the condition therefore differs from cystic fibrosis of the pancreas described by ANDERSON (*Am. J. Dis. Children* 1938 v 33 344). There was an indication that in the early stages the islets were hyperplastic later some seemed to disappear.

Attention was first directed to the pancreas because some patients admitted as diabetics in hyperglycaemic coma, when treated with insulin passed into hypoglycaemic coma which did not respond to treatment with glucose. At post-mortem the pancreas in such cases was found to be almost completely fibrosed. It was then discovered that fibrosis of the pancreas was extremely common. It was found in two-thirds of 165 routine autopsies and in every one of 13 cases of kwashiorkor. It is therefore suggested that pancreatic fibrosis is a kwashiorkor lesion, and that the disease is initially a result of pancreatic deficiency itself caused by malnutrition. This view is supported by the constant finding of undigested and unabsorbed food in the intestines. It could also explain the common but not invariable association of kwashiorkor with fatty infiltration of the liver since fatty liver has been produced in dogs by extirpation of the pancreas.

If this assumption is correct treatment should logically be directed to restoring pancreatic function. In this connexion the interesting observation has been made that one of the first signs of clinical improvement was swelling of the salivary glands which are closely related morphologically to the pancreas.

Oedema was the criterion used in selecting the cases described in these three papers. The syndrome as a whole, however, appears to be identical with kwashiorkor in Africa [The word is here used in its original sense (see WILLIAMS, *this Bulletin*, 1934, v 31, 344) and not with the wider meaning recently attached to it by TROWELL (*ibid.*, 1945 v 42, 306)]. The age incidence ranged from 4 months to nearly 6 years. Of 58 cases, 14 were white, 32 mixed, and 12 black. [The racial incidence is of interest because kwashiorkor has seldom been described in white children. It has been suggested that the disease is confined to peoples of African stock—a theory that can no longer be upheld in view of the present results from Brazil the observations of HANAFY (*this Bulletin*, 1948 v 45 458) in Egypt and earlier reports from Central America.]

The history was of a diet consisting almost entirely of carbohydrate. Diarrhoea was common. In many cases the presenting sign was oedema. This was of the dependent type, sometimes generalized and very severe. The skin was dry and inelastic, with branny desquamation. In most cases there was an extensive, diffuse hyperpigmentation, described as "Addisonian". Thirty-eight cases showed other skin lesions as well, most commonly there were irregular hyperpigmented patches with sharply defined edges and a more or less symmetrical distribution. The sites of election were the thighs, perineum, and gluteal region. The lesions began as discrete papules round hair-follicles, these became pigmented and coalesced, the pigmentation deepened, and the superficial layers desquamated leaving a delicate pink skin underneath. Biopsy of the skin showed atrophy of the basal and Malpighian layers with oedema and degenerative changes in the corium. These findings are illustrated in the first paper by photomicrographs. The lesions were more common in the black children than in the white or mixed. In other cases there were smaller hyperpigmented areas which appeared without initial erythema.

The hair was, in general, dry and depigmented, and the scalp covered with seborrhoeic crusts. In a few cases there was xerophthalmia. Angular stomatitis was common. The tongue usually showed atrophy of the papillae, although in some cases there was a frank glossitis. Examination of the heart showed tachycardia with marked sinus arrhythmia. Occasionally inversion of the T-wave was found in more than half the cases, and the calves were tender to pressure. The liver was usually enlarged, with a smooth regular edge, but the spleen was not palpable. At post-mortem, gross fatty infiltration of the liver was a constant finding. This was not related to the degree of enlargement. Other autopsy findings are not recorded. Evidence of osteoporosis was observed in X-ray examinations.

Laboratory examinations were mainly of negative interest. Helminthiasis was found in only a quarter of the cases. There was a variable degree of anaemia sometimes with a mild macrocytosis. Estimations on serum showed

in the mean values for calcium (7.39 mgm. per cent.) phosphorus (3.36 mgm. per cent.) cholesterol (88.5 mgm. per cent.) and phospholipids (8.1 mgm. per cent.). The total protein and albumin concentrations were very low but the globulin content was normal (means 4.13, 1.97 and 2.17 gm. per cent. respectively). The relation of these findings to oedema is discussed at length in the first paper. Although in most cases total protein and albumin concentrations were below the so-called oedema level this was not always so. Moreover in cases responding to treatment it was sometimes found that, as oedema disappeared the total protein and albumin concentrations did not rise but were even further reduced. It is suggested that the serum proteins may be not only reduced in quantity but also qualitatively altered in such a way that they do not exert their normal osmotic pressure and that under treatment the normal composition is restored before the amount.

Analysis of these findings showed that the condition was one of multiple deficiency involving protein minerals, vitamin A, thiamin riboflavin, nicotinic acid and probably other members of the vitamin B₂ complex. However at an early stage it was found that, in spite of the presence of signs of specific deficiency treatment with the vitamins concerned not only failed to cure but actually made the disease worse. Moreover none of the signs noted seemed to be in any way related to the severity of the general condition or to be of any value in assessing the prognosis. For these two reasons from the end of 1944 onwards attention was focussed on the fatty liver which was felt to be the central feature of the disease.

The harmful effect of vitamins was explained by the experimental findings of HANDLER, McHENRY and others that in rats choline-deficiency does not produce a fatty liver if B-vitamins are absent from the diet. Under the conditions of their experiments, when vitamins were given, the amount of fat in the liver increased. Moreover since diets low in the B-complex are likely also to be low in choline, it was logical to suppose that the fatty liver in these infants was the result of choline deficiency. This theory was tested by giving choline in various doses, and measuring the serum phospholipid content after an interval of 6-48 hours. It was thought that on current theories of the lipotropic action of choline, there should be an increase. No such increase was found, nor did there seem to be any beneficial effect on the general condition.

On the theory of choline-deficiency it was difficult to explain the presence of fatty liver in these infants in spite of an inadequate intake of B-vitamins as shown by the clinical signs of avitaminosis. Magalhães Carvalho and his colleagues therefore turned their attention to types of fatty liver that are not caused by choline-deficiency such as that produced in dogs by excision of the pancreas and cured by the pancreatic extract lipocac. Fifteen cases were treated with lipocac with apparent success. The authors are however careful to point out that the results were not significantly better than with milk alone and that the main point in treatment is to avoid giving vitamins. The results in detail were as follows —

| | |
|--|---------------------|
| Dried skimmed milk with vitamins, liver extract and plasma, etc. | 35 cases, 10 deaths |
| Dried skimmed milk alone | 8 cases, 1 death |
| Dried skimmed milk with lipocac | 15 cases, no deaths |

The rôle of the pancreas was further emphasised by the finding that in evenalescent cases there was a reduced secretion of pancreatic lipase and trypsin. These observations are briefly mentioned and not reported in full. The conclusion is drawn that in this syndrome the primary and essential lesion may be of the pancreas and not of the liver.

Comment

[The discovery of anatomical and functional lesions of the pancreas in kwashiorkor marks a new and important stage in our knowledge of the disease. It is remarkable that the same conclusion should have been reached independently and more or less simultaneously in three different parts of the world. In addition to the work of DAVIES and of MAGALHÃES CARVALHO, Professor VÉGHÉLYI has recently (*Lancet*, 1948, Mar 27, 497) reported from Budapest that when infants were deprived of milk during the siege, there was a decrease of pancreatic secretion which preceded the development of nutritional oedema and fatty liver. Such observations form a logical sequel to the earlier work of Scott BROWN and TROWELL [this *Bulletin*, 1945, v 42, 306] on the deficiency bowel pattern.

Atrophic changes in the pancreatic acinar cells were observed in infants with fatty liver in the West Indies [WATERLOW, this *Bulletin*, 1947, v 44, 841] but no conclusions were drawn about the relationship between the two lesions. Magalhães Carvalho implies, and Davies explicitly suggests, that fatty liver may be secondary to pancreatic damage, on the analogy of the fatty liver produced in dogs by pancreatectomy. This fits in with the fact that the disease does not respond to treatment with methionine [GILLMAN and GILLMAN, *ibid*, 1945, v 42, 748] or choline [MAGALHÃES CARVALHO, above, WATERLOW, *ibid*, 1947, v 44, 841, *Med Res Council Spec Rep Ser No 263*, 1948], whereas most workers have obtained good results with milk alone (Véghelyi, Magalhães Carvalho, Waterlow). The final link in the chain may be provided by the observations of FRIEDMANN and FRIEDMANN (*Canadian Med Ass J*, 1946, v 55, 15) who produced atrophic changes in the pancreas and fatty liver in rats on a diet low in protein.

If, as Davies suggests, kwashiorkor is essentially a pancreatic disorder, it would resolve a puzzling paradox. TROWELL [this *Bulletin*, 1941, v 38, 722, 1945, v 42, 306] has convincingly described the disease as a multiple deficiency state, involving almost all known factors. For this reason its limits have been extremely hard to define. At the same time, all observers have clearly felt that it is a definite disease, and this feeling has inspired a constant search for an essential lesion. The apparent contradiction would be removed if the essential lesion were one involving the splitting, absorption, and intestinal synthesis of nutrients.

It has become increasingly clear from the careful work over many years of Trowell, the Gillmans, and their collaborators, that kwashiorkor cannot be looked upon as an isolated episode of infancy or early childhood. Its consequences extend throughout life, since it may cause irreversible changes such as fibrosis of the pancreas and liver, and other lesions of which we know little. Moreover, even in adult life, the causes of kwashiorkor are never far away. The diet remains insufficient and unbalanced, so that the resulting picture is often very complex—of acute episodes superimposed, in the Gillmans' phraseology, on the chronic effects of a perverted metabolism.

Thus, even if it is established that the initial lesion is in the pancreas, there is much that remains to be discovered about the natural history of the disease and the relationship of its various features. In particular, great interest attaches at the present time to the pathological changes found in the liver, both in children and adults. It may therefore be of interest to examine in greater detail some of the observations in the papers summarized above.

In their earlier work Gillman and Gillman implied the existence of a close relationship between cytosiderosis of the liver and pellagra. This position led to difficulties. In the first place, cytosiderosis does not appear to have been found in pellagrins elsewhere, secondly, it tended to narrow the field of enquiry.

into the cause of the liver lesion. It is clear however from their present paper and that of Davies that liver lesions in Africans are almost universal: their distribution in fact is wider than that of pellagra, malignant malnutrition, or kwashiorkor in its infantile form (this *Bulletin* 1934 \ 31-344). Cytosiderosis cannot be regarded as a hallmark of pellagra, since it is equally common in non-pellagrins. It may therefore seem illogical to look upon monolobular fibrosis as the hallmark of kwashiorkor. This difficulty is avoided by the statement of Trowell that every African passes through a kwashiorkor phase manifested by pot belly and failure of growth. The connexion between this malnutritional phase and the ever present fibrosis cannot however be regarded as proven. This caution is dictated by the fact that whereas cirrhosis is admittedly common in malnourished peoples, this particular type of monolobular fibrosis seems not to have been described outside Africa.

In the case of fatty liver Davies has shown that this cannot be a kwashiorkor lesion since cases may present all the clinical signs of that disease with no fat in the liver. The complement of this has been found in the West Indies (WATERLOW *loc. cit.*). Infants may show gross fatty infiltration of the liver and die apparently from hepatic failure with oedema but none of the other manifestations of kwashiorkor. There was also evidence obtained by biopsy that milder degrees of fatty change were quite common in infants apparently healthy except for slight weight loss. Therefore it would seem that in babies fatty liver may be looked upon as a distinct entity an effect of malnutrition separable from other signs of deficiency. It is in no way specific to kwashiorkor but may also be found in malnourished infants in Europe as in cases of *milk-kwashiorkor* (Waterlow 1947 \ *ibid.*, 1948).

The conclusion then must be that liver lesions of various types (fatty change, cytosiderosis, cirrhosis) are widespread among the malnourished populations of the tropics but it is not yet possible to relate any particular lesion to a specific clinical picture.

When the papers of Davies and the Gilmans are considered together the question arises why should iron pigmentation be found in one group and not in the other? An answer is yet possible. Cytosiderosis, as far as present information goes, seems to be peculiar to the Rand whereas cirrhosis in one form or another is common throughout the tropics. An important observation which may be relevant has been made by GILMAN and GILMAN (1945). In refuting the view that cytosiderosis might be caused by anaemia, they pointed out that their patients were not anaemic, and did not suffer from malaria or ankylostomiasis. All these conditions are endemic in East Africa, and in most parts of the tropics. It is therefore possible that other things being equal the absence of cytosiderosis is related to the presence of diseases which increase the body's demand for and turnover of iron.

The end-results of fibrosis in the liver tend to be much the same whatever the initial cause. Therefore conclusions derived from experimental cirrhosis in animals cannot easily be applied to man until more is known about the development and early stages of the human disease. Davies's observations are here particularly valuable and go far to fill the gap although none of the types of dietary cirrhosis produced in animals corresponds exactly to monolobular fibrosis in man. It is not clear whether the workers in East Africa believe that fibrosis is in any way caused by fatty infiltration. In the West Indies the same picture was found, of a tumour-like growth at the edge of the liver lobule (WATERLOW *loc. cit.*). From the scanty evidence available it seemed that the end result was a fibrosis of the Laennec type similar to that produced in dogs with fatty liver by CHAMBERS and his co-workers (*Am. J. Path.*, 1943 \ 19-27).

This brief summary draws attention to three questions in relation to the liver lesions —

- 1 Is fibrosis caused by preceding fatty infiltration ?
- 2 Is fibrosis of the liver, as found in under-nourished peoples, a pathological entity, or does it have different modes of development under different circumstances in different parts of the world ?
- 3 What is the relationship of iron pigmentation to the other changes ?

It is clear that these questions can only be fully answered in the light of information from all parts of the world where malnutrition exists. In recent years the study of the more acute forms of the disease has gone forward with great speed in many different countries, and this gives great promise for the future.]

HAEMATOLOGY

GOSDEN, Minnie & REID, J D **An Account of Blood Count Results in Sierra Leone** *Trans Roy Soc Trop Med & Hyg* 1948, Mar, v 41, No 5, 637-40

This paper analyses the results of 1,035 total red cell and 1,005 white cell counts done on adult Africans at the Government Laboratory, Freetown, between 1943-1946

The chief object of the survey was to compare adult African blood standards with European "normals" and to determine the locally prevailing types of anaemia. The samples were those for routine examinations for anaemia or from patients who felt "run-down". The patients came from all social grades, but classification on a social basis was not possible in view of varying dietetic standards, such a classification would have been a factor of importance.

Many of the anaemias did not respond to either iron or liver therapy alone, and required a combination of both they probably corresponded with Trowell's dimorphic type [this *Bulletin*, 1943, v 40, 938]

Standard methods of examination were employed and are described and the European standards adopted for comparison were those given by WHITBY and BRITTON (*Disorders of the Blood*, 1942, 4th Edition London Churchill)

The results are shown in four tables. These show that 26 per cent of 661 men had red cell counts of at least 5 million cells per cmm and 72 per cent were at least 4 million about two-thirds of the latter had normal values for mean corpuscular haemoglobin and mean corpuscular volume. Of 377 women, 56 per cent had red cell counts of at least 4 million cells per cmm, and of these over half had normal MCH and MCV values.

In 109 moderate anaemias in men 57 per cent were orthochromic normocytic and of the 74 more severe anaemias 40 per cent were orthochromic and 39 per cent were normocytic. Hypochromic microcytic anaemia was about twice as common as macrocytic hyperchromic anaemia.

In 99 moderate anaemias in women, about half were orthochromic normocytic and this form was also seen in 64 severe anaemias. The microcytic hypochromic type was about 3 times as common as the macrocytic hyperchromic type.

The sickle cell trait was found in 27 per cent of all the bloods examined.

Of the white cell counts in 646 men and 359 women, 79 per cent were within normal limits and 5 per cent showed leucopenia, eosinophilia occurred in 40 per cent of men and 17 per cent of women and a monocytic increase was present in 34 per cent of men and 42 per cent of women.

During the same period, 7 cases of myeloid and 1 of lymphatic leukaemia were seen.

The authors conclude that in adult Africans in the Freetown area blood cell counts and haemoglobin levels appear to be within the accepted normal levels.

for Europeans that an orthochromic normocytic anaemia is the commonest type that microcytic hypochromic is commoner than macrocytic hyperchromic and that about one adult in four has the sickle-cell trait.

[It is now almost a platitude to observe that efforts to arrive at haematological and other "normals" in Africans are of prime importance and until acceptable physiological standards are arrived at many forms of pathological research must remain without an adequate foundation. Surveys of the kind described above are greatly to be commended but the difficulty still remains of assessing the normal "African" in the first instance—for example in the above series all the persons examined were patients complaining of some degree of ill-health. The present reviewer in a small study of the polynuclear count in East Africans many years ago (this *Bulletin* 1931 v 28 837) set out to obtain a control series of healthy Africans who would be sufficiently free of any disease—and particularly any infection—which might be likely to influence their haematological state. Experience showed what immense difficulties existed anything which clarifies the physiology of Africans in their present background increases the possibilities of understanding and therefore (rectifying their pathological status. See also HENNESSY this *Bulletin* 1937 v 34 256)]

BOTURLO Edg & BOTURLO Edm. Doença por hemátias falciformes (Sickle-Cell Disease). Incidência na Santa Casa de Santos—observações clínicas e hematológicas. [Observations on Cases of Sickle-cell Anemia in Santa Casa Hospital (Rio de Janeiro).] *Hospital. Rio de Janeiro* 1947 Nov v 32, N 5 709-28, 4 figs. [38 refs.] English summary

Three cases of this condition are described from among 20 detected in examining 294 coloured persons. 64 white persons were examined, but none of these was affected. Of the 294 there were 162 negroes and 132 mulattoes and those with sickle-cell numbered 14 and 8 respectively. The histories of the three were very different. One (No. 3 in the cases detailed) had fever, cough, and pain in the chest and was diagnosed as suffering from lobar pneumonia. A second (No. 2) had fever, palpitation, dyspnoea, tinnitus and prostration from weakness. The third (No. 1) in the midst of enjoying excellent health suddenly complained of "feeling very ill" and lost consciousness. He was brought to hospital in a comatose condition which persisted for 7 days and was followed by transient aphasia and dysarthria, so that no proper account could be obtained for 10 days and even then there was some degree of mental confusion but he remembered telling his fellow worker that he was feeling ill. Wassermann reaction was negative with both serum and cit. traspinal fluid. The blood changes are described fully and were those usually seen in this disease: the sedimentation rate was much reduced ranging between 3 and 15 mm. in the first hour. The erythrocyte count also varied widely. In No. 1 it was 3,480,000 and Hb 80 per cent. and 7 weeks later 4,400,000 with Hb 85 per cent. in No. 2, the first count gave only 800,000 per cmm. and Hb 30 per cent. 3 weeks later 2,000,000 and Hb 82 per cent. after another week he had another febrile attack and the red cells fell to 820,000 and Hb to 18 per cent., increasing in a fortnight to 1,740,000 and Hb 45 per cent. After this he improved slowly but at times complained of headache and giddiness and had occasionally bouts of fever to 40°C. No. 3 was not so ill: his counts ranged during the first ten days observation about 2-½ million per cmm. and Hb 60 per cent. and in another ten days the figures were 3,120,000 and 60 per cent. The residual red corpuscles in 0.2 per cent. saline in this patient became elliptical and remained so for 24 hours. These are regarded by the author as "regression forms of the sickled erythrocytes possessing greater resistance."

VENOMS AND ANTIVENOMS

MACCHIARELLO, A. Cutaneous Arachnoidism experimentally produced with the Glandular Poison of *Lasiopeltis*. *Puerto Rico J. Pub. Health & Trop. Med.* 1947, Dec., v. 21, No. 2, 260-79. 4 figs. Spanish version 280-93.]

Study has been undertaken of the poison or poisons of the spider *Lasiopeltis* which occurs in Antioquia, Chile. The lesion produced in man is known as 'gugigerous spot'. The spider abounds in damp, dark and dry places, and many were captured in mud and straw hut. Experiments were made with rabbits, rats and white mice at first, but later guinea pigs were used solely. The lesion is caused by severity from oedema without induration, to oedema with induration and to a urticarous spot followed by necrosis and ulceration. In man the same sequence of events occurs, but without general systemic disturbance. The severity differs from one spider to another, and whether the bite (or sting) is the first or not, and whether the insect has been kept caged and fasting. Stings of the black or greenish black specimens are the worst, they are usually the young ones. The more concentrated the poison (that is glandular matter ground up and emulsified in saline) the less intense the reaction: this is ascribed to the fact that the concentrated poison causes coagulation of the tissues and this impedes diffusion. The glandular poison seems to act only on or in the skin: it is not haemolytic. The arachnoidism extracted from the cephalothorax or abdomen differs in its action from the glandular poison from the fangs and there is no cross-immunity between them. Moreover, the arachnoidism is strongly haemolytic for guinea pig erythrocytes and still more for rabbit corpuscles and is not necrotising.

DERMATOLOGY AND FUNGUS DISEASES

LEÓN BLANCO, F. & DE LAOSA, O. The Primary Lesion of Pinta (Mal del Pinto or Carato). *Amer. J. Syph.* 1947, Nov., v. 31, No. 6, 600-609, 9 figs.

There are three stages in the clinical course of pinta, the initial lesion, secondary widespread skin lesions or pintides and the tertiary dyschromic stage. The present study was presumably carried out in Cuba.

Five to ten days or earlier after infection a small papule develops. By the 20th to 26th day it is larger flat and slightly desquamating. By the 30th-50th day the lesion is a flat reddened scaly patch. Satellite papules may develop and later coalesce with the enlarging initial lesion. The final appearance may resemble psoriasis, trichophytosis, lichen or may be that of large pink desquamating patches with infiltrated edges which are often separated by atrophic skin.

In the early papular stage, itching is constant but it is less marked later. The initial lesion is usually on an exposed part of the body especially the leg and dorsum of the foot (63 per cent. of 257 cases) and the forearm and dorsum of the hand (22 per cent.).

The disease is usually acquired during the first two decades of life but begins after the first year or so.

The lymphatic glands, in the primary and secondary stages are enlarged, painless and movable.

The incubation period in experimental infections is 3-10 days, but longer periods up to 60 days, have been reported.

In 39 naturally acquired infections of 40 days to two years duration, the serologic flocculation and complement fixation tests were negative. In 17 experimental infections the reactions became positive after the appearance of pustules.

The histopathological changes in the initial lesion include acanthosis with increased length of narrow rete processes, active infiltration by lymphocytes and polymorphonuclear cells and the development of oedema. In the cutis there is peri-vascular infiltration by lymphocytes and plasma cells. Tissue-macrophages are numerous, particularly in the epidermis. [The illustrations of initial lesions are excellent.] (See also this *Bulletin* 1945, v 42, 584.)

ALLEN A. C. Persistent "Insect Bites" (Dermal Eosinophilic Granulomas) simulating Lymphoblastomas, Histiocytoses, and Squamous Cell Carcinomas. *Amer J Path.* 1948, Mar v 4 No. 3 357-87 24 figs. on 6 pls. [11 refs.]

This article describes the histology of the cutaneous reactions to "bites" of ticks, chiggers, mosquitoes and unidentified arthropods. The author emphasizes that these reactions may last as long as two years and may exhibit a very variable microscopical picture. The cellular reaction in the dermis, characterized by large numbers of eosinophilic leucocytes, plasma cells and histiocytes, may be mistaken for Hodgkin's disease, mycosis fungoides, atypical lymphoblastoma, histiocytoses or the eosinophilic granular group. An appearance closely simulating that of squamous-cell epithelioma may be produced by a section which cuts obliquely through the hyperplastic epidermis and its branching rete pegs. No difference was noted in the histological reaction to bites of the various arthropods except for the almost complete absence of eosinophilic leucocytes in the eschar of scrub typhus caused by the larval mite (*Trombicula akamushi* and related species).

H. F. H. Wood

JOLLY H. R. Prevention of Ringworm in the Tropics. *Brit Med J* 1948, Apr 17 738-8, 1 graph

This article describes an experiment in the control of ringworm in the Netherlands East Indies where the disease had reached epidemic proportions and very severe cases were not uncommon. Four hundred British troops were selected for the experiment, which aimed at the prevention of spread of infection from the feet of one soldier to those of another.

Two pairs of underpants were issued to each man, and these were washed and changed daily. Each man was given two foot-towels, which were used on the feet only, and were washed and changed daily. Clogs were provided to be worn in the bathroom, where showers were used and not baths. This enabled the toes to be washed without removal of the clogs, and consequently the feet were never brought into contact with the bathroom floor. The men were not allowed to walk bare-footed around the buildings.

Infected cases were not segregated, and the following routine treatment was used with occasional modifications —

Lesions on the body — One per cent chrysarobin in Lassar's paste

Lesions on the face — Whitfield's ointment

Lesions between the toes — Brilliant green 1 in 500 in spirit with 3 per cent salicylic acid

By these means, the number of new cases of ringworm was reduced from 91 in May 1946 to 13 three months later, and this result was achieved without interference with the normal working routine

HOWELL, A, Jr. The Efficiency of Methods for the Isolation of *Histoplasma capsulatum*. *Pub Health Rep* Wash 1948, Feb 6, v 63, No 6, 173-8, 3 figs on 2 pls [11 refs]

From the spleens of 79 guineapigs experimentally infected with a single strain of *Histoplasma capsulatum*, sowings were made in duplicate on two different culture media, brain-heart-blood-agar and potato-dextrose-agar with penicillin and streptomycin added. One set of cultures was incubated at 37°C and the other at room temperature.

Of the cultures incubated at room temperature, 35 out of 46 (76.1 per cent) on brain-heart-blood-agar and 19 out of 46 (41.3 per cent) on potato-dextrose-agar were successful, while those incubated at 37°C yielded only 6 successful growths out of 46 sowings on brain-heart-blood-agar and none on potato-dextrose-agar. These results would indicate that brain-heart-blood-agar is a more suitable medium than potato-dextrose-agar and incubation at room temperature much better than at 37°C. [It should be noticed, however, that only a single strain of *H. capsulatum* was used, and strains of this species vary in their adaptability to saprophytic vegetation at 37°C.] [Only the mycelial form of the fungus is mentioned in the paper and it is well known that the optimal temperature for vegetation in this form is far below 37°C; in fact some strains cannot vegetate in the mycelial form at this temperature. On the other hand, 37°C is the optimal temperature for vegetation in the yeast-like form and, on blood-agar at this temperature yeast-like primary cultures frequently develop. Subject to this qualification, the author's findings are in harmony with the general experience of mycologists.]

CROSS, F W & HOWELL, A, Jr. Studies of Fungus Antigens. II. Preliminary Report on the Isolation of an Immunologically Active Polysaccharide from Histoplasmin. *Pub Health Rep* Wash 1948, Feb 6, v 63, No 6, 179-83

The polysaccharide fraction was isolated from crude histoplasmin by precipitation with ethyl alcohol (4 vols of 95 per cent) after previous removal of the protein fractions. The yield of dry polysaccharide was approximately 0.34 mgm per ml of the crude solution. Tests of dermal sensitivity made on a group of guineapigs experimentally infected with *Histoplasma capsulatum*, and a number of normal control animals showed the polysaccharide to be an effective reagent. Compared with the stock, crude histoplasmin, and desiccated

crude material, the polysaccharide at a dose of 0.1 mgm. in 0.1 ml. gave a positive reaction in 83.9 per cent. of the guinea-pigs sensitized with *H. capsulatum* histoplasmin at a dose of 0.1 ml. of 1:100 solution, in 85.3 per cent. and desiccated histoplasmin at a dose of 0.1 mgm. in 0.1 ml. in 81.6 per cent. Lower proportions of reactors and smaller reactions were given by all three reagents when they were used in lower dosage but even at the dose of 0.001 mgm. per ml. the polysaccharide gave positive results in 45.5 per cent. of the animals.

As the polysaccharide fraction represents only about 1 per cent. of the total solids of histoplasmin, it seems that there are other antigenic fractions in the crude material.

To test for cross reactions guinea-pigs infected with *Blastomyces dermatitidis* which were highly sensitive to blastomycin, were used with the histoplasmin polysaccharide. The proportions of positive reactors at the various doses were as follows: 0.1 mgm. 48.1 per cent., 0.01 mgm. 25.9 per cent. and 0.001 mgm. 3.7 per cent. The comparable proportions with *Histoplasma* inoculated animals were 83.9 per cent. 78.8 per cent. and 45.5 per cent.

TEENBERG D. J. HOWELL, A. JR. FURCOLOW M. L. BUXNELL, L. L. A Complement Fixation Test for Histoplasmosis. I. Technic and Preliminary Results on Animal Sera [TEENBERG & HOWELL] *Pub. H. and Rep. Wash.* 1948 Feb. 8 63 No. 8 163-8. II. Preliminary Results with Human Sera [FURCOLOW BUXNELL & TEENBERG] *Ibid.* 169-73.

The significance of dermal sensitivity to histoplasmin in the absence of clinical and mycological evidence of active histoplasmosis remains undetermined. It is imperative therefore that the diagnostic value of serological tests in this disease should be explored.

I. The first paper deals with the complement fixation test applied to the serum of experimentally infected guinea-pigs. The antigen used was the 1:100 dilution of the histoplasmin skin test reagent (H.15) and the technique was based on Kolmer's modification of the Wassermann test. Of the sera from infected guinea-pigs 8 out of 1 gave complete fixation of complement while sera from 33 uninfected guinea-pigs all gave negative results. Cross reactions between *Histoplasma* antiserum and *Blastomyces* antigen (the 1:100 blastomycin skin test reagent) and between *Blastomyces* antiserum and *Histoplasma* antigen occurred but by preparing serial dilutions of the serum a point could be reached at which complement fixation was given only with the homologous antigen. These cross reactions when relatively low dilutions of the sera are used are in harmony with the cross reactions described by HOWELL *Bull. of H. Gen.* 1947 v. 22, 569 in connexion with the histoplasmin and blastomycin skin sensitivity tests. Dilution of the crude antigens beyond the stock 1:100 strength greatly weakened the reaction, and it is suggested that a much stronger antigen or a purified preparation should be used. It is also suggested that the immune bodies on which dermal sensitivity and the complement fixation tests depend may not be identical and the complement fixation test should provide better diagnostic evidence of existing infection.

II. The second paper deals with the application of the complement fixation test to human sera following the technique used in the tests on guinea-pig sera. Complete complement fixation was given with 8 out of 9 sera from proved cases of histoplasmosis. 7 out of 13 sera of persons (chiefly children) who, after an earlier negative skin test result were found to have developed dermal sensitivity to histoplasmin which suggests recent infection, and 8 out of 38 sera of persons, with active pulmonary lesions who were histoplasmin positive and tuberculin-negative. Allowance should be made for the probability that

some of the sera had been collected after the specific antibody titre had fallen. Control sera numbering 242 from various sources, including 58 from persons who were histoplasmin-positive and tuberculin-negative, gave entirely negative results.

In the case of proved histoplasmosis there was a close parallel between the results of dermal sensitivity tests and the complement-fixation test.

This serological study offers the hope of a valuable additional means of diagnosis, in the complement-fixation test, and it lends support to the view, based mainly on the evidence of dermal sensitivity to histoplasmin, that histoplasmosis may exist in an undetected, subclinical form. J. T. Duncan

HARVEY, N. A. **Progressive Coccidioidomycosis. Report of a Case.** *Ann Intern Med* 1948, Mar, v 28, No 3, 651-61, 2 figs [25 refs]

"A case of progressive coccidioidomycosis is presented with clinical data and necropsy findings. A generalized coccidioidal peritonitis found at autopsy was apparently caused by the intraperitoneal release of infective material from necrotic liquefying nodules on the surface of the spleen and liver. The complement fixing antibodies never gave a positive test in dilutions greater than 1/8, and the patient became anergic to intradermal injections of coccidioidin (1/100 dil) in the terminal stages of the disease. A total of 6,260,000 units of penicillin was given with no demonstrably beneficial clinical effect. Many analogies can be drawn between coccidioidomycosis and tuberculosis. A brief discussion of some aspects of the disease is presented."

FURTADO, T. A. & PELLEGRINO, J. A terapêutica da blastomicose Sul-Americana, ensaios "in vitro" com a estreptomicina [Treatment of South-American Blastomycosis. Trial of Streptomycin "in vitro"]. *Brasil-Médico* 1948, Feb 21 & 28, v 52, Nos 8/9, 54-6 [20 refs] English summary

The authors show, by references to the literature, the unsatisfactoriness of the treatment of *Paracoccidioides brasiliensis* infections. They mention local injection of 10 per cent sodium iodide by Magalhães, methylene blue by Pupo, these same two drugs with sodium cacodylate by Prado, and the varying results recorded of these, the failure of tartar emetic, gonacrine, trypanflavine, arsenicals, sulphapyridine and other sulphonamide drugs. Tyrothricin was favourably reported upon from *in vitro* experiments by Lacaz and Cury, but *in vivo* this could be used locally only because parenterally it was toxic and haemolytic. Now, the authors have tested streptomycin in dilutions from 500 microgrammes to 1 microgramme per cc on cultures in Sabouraud glucose. Twelve days later growth had been inhibited in the two strongest, partial in the 300 per cc, but not in the others and even with the first two growth took place unimpaired on transfer to fresh medium. The action is, therefore, fungistatic only, and not fungicidal.

H. Harold Scott

BROCKMAN, D. D. **The *in vitro* Effect of Atabrine on *Cryptococcus neoformans*.** *Amer J Trop Med* 1948, Mar, v 28, No 2, 295-7 [11 refs]

"Atabrine is fungicidal *in vitro* at concentrations of 25 to 50 mgm per cent and fungistatic at 3 to 25 mgm per cent for *C. neoformans*. Toxic reactions are obtained with much lower plasma or tissue concentrations. Atabrine is, therefore, of little therapeutic value in cryptococcus infections."

TROPICAL OPHTHALMOLOGY

A REVIEW OF RECENT ARTICLES. L

Parasitic conditions.—A case of Trombiculid mites on the eyelid is described by BOASE¹. The skin of the lash-bearing area of the left upper eyelid presented a reddish powdery appearance. At the first glance this was thought to be red murrain dust or some form of native medicinal powder but on closer examination the dots were seen to be uniform in size individually of a bright red colour and evidently red mites. On identification, these proved to be the larvae of the genus *Trombicula*. This genus is the vector of scrub typhus in South-East Asia. The evidence in this case suggests that infestation occurred in the Ankole district of South-West Uganda.

Complete up-to-date literature of ocular sporotrichosis is reviewed by GORDON². Forty-eight cases have been reported in the world literature. Apparently in 34 of these cases, the ocular disease was primary and in 14 secondary to involvement elsewhere in the body. In two of these cases the diagnosis was in question. Of the 48 cases, 10 have occurred in the United States of America and the majority of the remainder in France.

The disease in the eye most commonly manifests itself as ulcers of the lids and conjunctivae. These tend to begin as large subcutaneous gummas and break down to form ulcers. The latter are deep and may even develop in the bony walls of the orbit. The eyeball itself can be implicated in three ways—by direct trauma, by direct extension, or by the blood stream.

The author's case was in a woman aged 48 years, who came to the eye clinic complaining of a "sore" on her upper eyelid. There was no definite history of trauma, but about a week prior to the onset she had been working in her garden among palmettos. There were marked swelling and redness of the eyelid with a granulation ulcer in the centre. The globe and the lachrymal apparatus were not involved. A culture on Sabouraud's medium was made from the material taken by aspiration from a nodule near to the ulcer. This five days later revealed *Sporotrichum schenckii*. The patient was treated with a saturated solution of potassium iodide. The initial dose was 10 drops four times a day. This dose was gradually increased up to 25 drops four times a day and she responded well to treatment. The average period of medication is from one month to six weeks.

Trachoma.—The treatment of 600 cases of trachoma by sub-conjunctival injections of sulphonamide is discussed by BIZANT³. These comprised the very early cases, those in the follicular stage, those with active corneal complications, and those with scar tissue formation. The results were excellent.

He has formed the following conclusions:—The accompanying conjunctivitis rapidly disappears. The usual distressing symptoms quickly improve or disappear, the follicles on the tarsal conjunctiva smooth down and become less prominent. In corneal trachoma the improvement is very marked and rapid. Ulcers and abscess of the cornea with hypopyon be not improved after the first injection, the cornea losing its angry appearance with rapid clearing up of the zone of infiltration and cicatrization occurring after a few days. Laminar opacities becomes less intense and quickly smoothes down and retrogrades. Diffuse opacities of the cornea become less in extent, the cornea becoming more

BIZANT, P. Essais de traitement de trachome (600 cas), par de injections sous-conjunctivales de sulfonamide thioverbe. *Bull. Soc. Path. Exot.* 1947. 4. No. 78, 277-84.

transparent with considerable improvement of vision in many cases. Those cases with xerosis and infections of the uveal tract show no improvement.

In the ordinary cases, there are no contra-indications to the use of the drug. Pain sometimes occurs, especially after the first injection and occasionally a slight haemorrhage appears after the injection.

The dosage recommended is $\frac{3}{4}$ to 1 cc of the solution. [No mention is made of the exact composition of sulphonamide used or the strength of the solution.]

Leprosy—The effect of Grenz rays on leprosy infiltrations on the anterior portions of the eyeball is discussed by SAGHER and MITERSTEIN⁴. Lepromas on the bulbar conjunctiva close to the limbus are somewhat amenable to local therapy, unless the process has penetrated too far into the eye or originates from the ciliary body. The usual treatment of these lepromas consists in the application of solid carbon dioxide, the local injection of various drugs, and surgical measures. In previous experiments with irradiation, it was found that cutaneous lepromas were noticeably affected by the Grenz rays and the results were fairly good.

The authors treated 6 patients in whom there were lepromatous changes in the anterior segments of the eyeball. Three practically sightless eyes were first exposed to these rays and in all 3 patients the lepromas became reduced in size or disappeared completely. When the Grenz rays were employed on the eyes of 3 additional patients which presented lepromas with fairly good vision, two eyes exhibited a favourable response, and in the third the lepromatous part became quiescent or even slightly flatter, while the surrounding parts presented rapid growth of new lepromas. The voltage of the rays used ranged from 6 to 14 kilovolts, which is equivalent to half value layers of 0.021 to 0.031 mm of aluminium. The most effective doses applied at one sitting were from 700 to 1,200 k, the total amount varying from 5,500 to 11,600 k.

These large doses could be applied safely to the external tissues of the eye, because the sensitivity of such tissues to rays is lower than that of the skin. No damage to the cornea, lens or deeper structures of the eye was noted, so far as this could be determined on the basis of observations extending over a period of between two and four years.

Optic neuritis—A case of trypanamide optic neuritis treated by 2,3 dimercaptopropanol (BAL) is reported by FRIEDENBERG⁵. The case was one of tabes dorsalis due to syphilis which was treated for six months with intramuscular injections of sodium iodobismuthite and a course of penicillin. These were followed by two intravenous injections of 0.7 gm and 1.0 gm of trypanamide at a week's interval between the injections. Two days after the second injection the patient complained that he could not see the sidewalk when walking. Examination confirmed the loss of the inferior visual fields and that he was suffering from optic neuritis. He was at once put on BAL therapy. The first two days he was given 300 mgm twice daily and the following eight days he was given 300 mgm daily with the exception of the fifth day, when 400 mgm were given. Several hours after this injection he complained of paraesthesias in the left side of his neck and jaw. This lasted about one hour. Vision returned nine days after BAL therapy was stopped. On examination six months later the visual fields showed great improvement and the acuity of vision remained normal. The author is of opinion that the unusually rapid return of vision was probably due to the prompt use of BAL as soon as the patient complained of visual disturbance.

splenectomy was done for traumatic rupture and in five for splenomegaly. In both the patients with traumatic rupture a quiescent period, lasting in one case for three days, preceded the onset of acute symptoms.

W. L. Harnett

ELMES, B. G. T. & BALDWIN, R. R. T. Malignant Disease in Nigeria: an Analysis of a Thousand Tumours. *Ann. Trop. Med. & Parasit.* 1947, Dec. v 41, Nos. 3 & 4, 321-8, 4 figs. on 2 pls. [13 refs.] [Summary appears also in *Bulletin of Hygiene*.]

In a paper published in 1934 and abstracted in this *Bulletin* [1935, v 32, 522] SMITH & ELMES gave a detailed analysis of 500 consecutive malignant tumours which had arisen in Nigerian Africans and had been submitted to pathologists in that country for identification. The present paper is a summary of 1,000 additional tumours from the same source. The tumours correspond in nature and incidence fairly closely with those recorded in the earlier paper. The youth of the patients is again noticeable, 248 of the 1,000 having been under thirty years old. Of all the tumours 81 per cent. began in the liver and were associated with subacute necrosis and cirrhosis of the Laennec type. Attention is specially drawn to those conditions in which the causation is not entirely obscure. Among these besides the liver cancer which are largely due to erroneous feeding, are many epitheliomas growing in leg ulcers, five cases of scrotal cancer and ten of cancer of the penis. Of 18 instances of malignant disease of the bladder only four were accompanied by *Schistosoma haematobium* infection, despite the frequency of this malady in Nigeria. Notable features among the thousand tumours analysed are the relative frequency of melanoma (6.2 per cent.), mixed salivary tumour (4.9 per cent.) and adamantinoma (1.8 per cent.). The paper though brief, contains several other items of interest and should be read in the original.

Harold Burrows

PROTOZOOLOGY GENERAL

HEALY, B. H. & GROCOTT, R. G. Congenital Toxoplasmosis. *J. Amer. Med. Ass.* 1948, Jan. 10, 136 No. 2, 104-8, 11 figs. [Refs. in footnotes]

The case described was in an infant prematurely born after 6½ to 7 months of pregnancy. The infant died 10½ hour after birth. A post mortem was performed 31 hours after death, the body having been kept in the refrigerator at a temperature of 33 to 38 F. The brain was a collapsed gelatinous mass and was covered by haemorrhagic leptomeninges. Histologically areas of focal necrosis with extensive deposition of calcium salts occurred. The eye showed extensive chorio-retinitis. *Toxoplasma* were found in the brain, eye and many other organs. Inoculated with brain material, guinea-pigs acquired an infection which was maintained by sub-inoculations. Attempts to demonstrate a latent infection in the mother failed, but a serological protection test was not carried out. This is the first case of congenital toxoplasmosis to be described from Panama.

C. M. Hearn

RICHMAN, I. Occurrence of *Toxoplasma* Neutralizing Antibodies in various Disease Conditions. *J. Lab. & Clin. Med.* 1948, Jan., v 73, No. 1, 67-68, 13 ref.

The *toxoplasma* neutralization test of SABIN was employed to determine the presence of antibodies in various diseases. Of the sera from 100 selected individuals twenty-one per cent. were found to be negative and four doubtful. The

was a high incidence of positive sera amongst children showing signs of congenitally acquired toxoplasmosis—convulsions or other signs of central nervous system involvement and hydrocephalus or microcephalus when these were associated with chorioretinitis or cerebral calcification. The blood of the mothers of such patients regularly showed antibodies. Antibodies were also found in a child with prolonged encephalitis and in two adults with mental disturbances. The antibodies persist in the blood stream for at least five years. Many conditions of obscure aetiology failed to show the presence of antibodies.

ENTOMOLOGY AND INSECTICIDES GENERAL

MACKERRAS, I M The Jackson Lecture Australia's Contribution to our Knowledge of Insect-borne Disease *Med J Australia* 1948, Feb 7, v 1, No 6, 157-67 [Bibliography]

The lecture gives a readable general account of the development of our understanding of insect-borne diseases. It pays particular attention to Australian problems and the work carried out in that continent. It gains much because the author has a first-hand knowledge of some parts of the work and also because of the excellent list of selected references. Like many other general papers, it is difficult to summarize.

The author gives a general classification of his subject, pointing out that there are many different types of relationship between the arthropod and the mammal. He then develops the subject historically under three periods. In the first of these, most of the major discoveries were made and the period might be said to be one of zoological observation. So far as Australia is concerned, it started in 1876 with the discovery by Joseph Bancroft of the adult nematode which was called *Filaria bancrofti* by Cobbold. This first period ended at about the year 1900.

During the second period, which occupied the first twenty-five or thirty years of this century, few major discoveries were made except in the life histories of rickettsiae, but results worked out in one area were plotted or confirmed in many other parts of the world, and the sciences of parasitology and medical entomology may be said to have been established. During this period, Australian workers made important contributions to knowledge, particularly the relation to plague, dengue and filariasis. They also carried out most useful surveys of the parasites of Australian vertebrates.

In the third period, which commenced between the world wars, experimental and physiological studies were developed, founded on the earlier observations, so that there was a great elaboration of technique. In medical entomology, ecology and the closely related science of epidemiology began to take a large place. Australian workers covered a wide field. One might perhaps refer particularly to their virus research and that on infections of the typhus group, which became of such importance during the war period. Here the author records with legitimate pride that it was an Australian who brought in the use of the phthalates to kill the *Trombicula* and showed how they could be applied in the field. Outstanding Australian work on many sides of malaria must be familiar to all. It is less well known that when an epidemic resembling dengue appeared in jungles in New Guinea, it was shown that the infections were carried by a jungle mosquito *Aedes scutellaris*, infected material being taken by air to Australia where the experimental proof was completed.

P A Buxton

FREGUSON M. S. & GRAHAM O. H. *Phlebotomus* in New Guinea and Nearby Islands. *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948 Mar v 41 No. 5 679-84 2 figs.

Adults of *Phlebotomus* as yet undescribed, were collected from tree holes, trunks and buttresses. For the collection of living sandflies, tobacco smoke was used. Later the Freon aerosol bomb was employed and the flies fell on to a white cloth and died. No *Phlebotomus* were taken in fox-holes or in pill-boxes. Fallen trees and light traps yielded none though other members of the family were sometimes numerous.

A table is given of the data concerning the collections and a map shows where the collections were made. The rôle played by *Phlebotomus* in the transmission of disease was not determined. It is expected that descriptions of these sandflies will be published in due course. H. S. LARSON

BRENNAN J. M. An Instance of the Apparent Toxicity of Man to Ticks. *J. Parasitology* 1947 Dec., v 33 No. 6 491-4

The man to whom this paper relates was apparently perfectly healthy, scrupulously clean, exceptionally hairy, and was not addicted to narcotics or alcohol. His only excess was to drink as many as 20 cups of coffee each day. Adult ticks (*Dermacentor andersoni* and *Amalymma americana* var.) held in contact with his skin (in the antecubital fossa) for some 10-40 minutes, were always rendered immobile. They revived within 24 hours but never became quite normal. Nymphs of *D. andersoni* held in the same place or in the closed hand were killed in 3-10 minutes. Controls on other persons were entirely unaffected.

On the other hand, adult ticks and nymphs applied to parts of the skin free from sweat behaved irregularly: some were affected and others not. Ticks held near the skin but not on it were not affected. It was not possible to collect a quantity of sweat sufficient for a real test, but ticks placed inside a rubber glove worn by the subject of the experiment and containing a trace of sweat were not affected. His urine was harmless to them.

The ticks were obviously repelled, as well as intoxicated. It seems likely that there is some substance, presumably associated with the man's sweat which is both toxic and repellent. The condition is rare since no suggestion of it was found in 70 volunteers to whom ticks were similarly exposed. If this substance could be isolated, results of far-reaching value might be obtained.

Charles H. Stocks

HIRANT H. & BAUR, O., Mlle. Sur la présence en France de *Dermacentor ricinus* (Neumann, 1897). [The Presence in France of *Dermacentor ricinus* (Neumann, 1897)] *Bull. Soc. Path. E. et* 1947 v 40 Nos. 11/12, 463.

The authors found a male specimen of *Dermacentor ricinus* on the scapular region of a Mongolian child of 5 who was under treatment in the neighbourhood of Lodève (Hérault). This child had a continuous fever of 39 to 40°C on the day of examination and on the five following days. No other signs, cutaneous or visceral, were found in the patient.

The common hosts of *D. ricinus* are the sheep, camel and wild boar. It is possible that the tick was dropped from some animal in the meadows where the child was accustomed to play. It is evident that, although as far as the authors are aware, this species has not been reported from France before, it does occur, can attach itself to man and had a possible bearing on the febrile attack of the child who accidentally acquired it.

The authors assume that *D niveus* cannot be regarded as a simple variety of *D reticulatus* (Fabricius, 1794) a species well known in Europe and commonly known to-day as *D marginatus* (Sulzer, 1776)

H J O'D Burke-Gaffney

GARNHAM, P C C The New Insecticides East African Med J 1948, Jan , v 25, No 1, 5-10

This paper discusses the use of DDT and Gammexane and particularly describes experiments carried out in recent years in East Africa in the control of insect borne diseases The use of the newer insecticides in the control of malaria, relapsing fever and onchocerciasis is described , the results of relevant experiments have already been abstracted in this *Bulletin* from time to time The author also gives a brief description of the use of these insecticides in the control of *Aedes aegypti* and of common domestic pests

H J O'D Burke-Gaffney

DRESDEN, D & KRIJGSMAN, B J Experiments on the Physiological Action of Contact Insecticides Bull Entom Res 1948, Feb , v 38, Pt 4, 575-8 [12 refs]

The toxicity of an insecticide to an insect or vertebrate can be determined from external applications or by injection into the body cavity Data obtained by other workers are summarized and further results obtained by the authors with a cockroach a stick insect and a frog are tabulated According to these comparisons, the internal toxicity of DDT, Gammexane and Rotenone are of the same order to vertebrates and to insects But the vertebrates require much higher external doses, showing that their skins are effective barriers to this type of poison, whereas the insect cuticle is readily penetrated

The toxicity to *Periplaneta* of the various isomers of hexachlorocyclohexane was investigated It was found that, even after injection, the gamma isomer is outstandingly effective , its toxicity, therefore, is not due merely to its ability to penetrate the cuticle

In view of the suggested connexion between Gammexane poisoning and meso-inositol, tests were made in which cockroaches were injected with both separately and with various mixtures The inositol (which was itself innocuous) showed no sign of reducing the toxicity of the Gammexane

J R Busvine

JONES, B M Preliminary Tests of DDT Emulsion Concentrates Bull Entom Res 1948, Feb v 38, Pt 4, 585-90, 2 figs

The following emulsion concentrates were tested , Nos 1, 3 and 4 "soluble oil" type , No 2 "mayonnaise" type Nos 1 and 2 had solvent naphtha as a solvent for the DDT whereas Nos 3 and 4 had a toluene-turpentine mixture The DDT content of these concentrates ranged from 23 to 30 per cent

A simple test of stability was to prepare 1 per cent DDT emulsions from all concentrates and to observe how soon the emulsions would break Nos 1 and 2 were stable for twenty-four hours, but Nos 3 and 4 separated into two layers in thirty minutes and had broken in twenty-four hours The initial separation of Nos 3 and 4 was delayed by the normal agitation of a man using a knapsack sprayer Attempts to prepare 1 per cent dilutions with salt water (4.5 per cent salinity) were only successful with the "mayonnaise" formula

As a small field trial two rooms were sprayed with emulsions diluted to 5 per cent from concentrates Nos 1 and 2, to give about 200 mgm DDT per sq ft Mosquitoes (*Anopheles obturbans* and *Culex gelidus*) were liberated in the

treated rooms, for various periods, at intervals up to sixty days after treatment. The exposure necessary to produce 100 per cent. kill rose from about an hour to ten hours, but the loss of activity was not more rapid than with a kerosene-DDT treatment.

J. R. BURNIE

BRENNAN J. M. Field Tests with Tick Repellents. *Pub. Health Rep. Wash.* 1948, Mar 12, v 63 No. 11 339-48.

Field trials of tick repellents were arranged by the Rocky Mountain Laboratory, Hamilton, Montana, in collaboration with the U.S. Army. Men wearing fatigue kit were exposed to heavy attacks of *Ambyomma americanum* for about four hours per day for eight days in one trial and for ten days in another trial. The uniforms had been impregnated with one or two ounces of the various repellents (a pair for each treatment and four controls). Ticks acquired were removed and counted at intervals. The results are a little difficult to interpret because some of the treatments were more effective than others at first but did not last so well. Some were only highly effective against nymphal ticks while others were also good against the adults. However the following conclusions seem justified --

From the standpoint of maximum repellency butylacetanilide and benzyl cyclohexanol were first and second in all tests. Butylacetanilide also showed indications of promise as a mite (chigger) repellent. Although there are no data regarding its toxicity to mammals it is known that related compounds are harmless. There were no adverse reactions in the soldiers who wore the impregnated clothing.

Benzyl benzoate and dimethyl phthalate were also included in the tests. They gave rather erratic results especially against adults, but their repellence was fairly high and in view of their availability and safety they should be used against ticks at present.

Dibutyl phthalate and the "6 2 2" mixture gave rather poor results against ticks. [The 6 2 2 mixture contains 60 per cent. Dimethyl phthalate 20 per cent. Indakone 20 per cent. - ethyl-1 3-hexanedio.]

REPORTS SURVEYS AND MISCELLANEOUS PAPERS

ROSS INSTITUTE OF TROPICAL HYGIENE. LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE. Report of the Eighteenth Meeting of the Ross Institute Industrial Advisory Committee, 6th January 1948. [WIGGLESWORTH A. Chairman] 23 pp. 1 diagram

This is an account of a meeting at which the chairman, Mr Wigglesworth referred to the opening of the new branch of the Ross Institute at Tanga, in Tanganyika Territory. A paper was read by Dr TREDDER on the East African labourer in which he remarked that 90 000 men are employed on estates in Tanganyika, half of them round Tanga. These men suffer much from malaria, hookworm infestation and anaemia, and are often underfed. A haemoglobin content of only 60-70 per cent. is not uncommon in men who make no complaint of illness. Although the Government have laid down a minimum allowance of 2 600 Calories for labourers, it is not possible to be sure that each man gets the amount in full, or prepares the food adequately for consumption.

Papers on the eradication of *S. malinum* from streams in Kenya, by the use of DDT and on mass treatment in the control of schistosomiasis in Southern Rhodesia, were read by Dr GARNHAM and Mr ALVES. Papers on these subjects

have already been reviewed in this *Bulletin*. Alves makes the important point that the opening up of African water supplies for hydro-electric, irrigation or even domestic use, will mean corresponding extension of the area in which the schistosome-bearing snails are to be found, unless the engineers seek the advice of public health workers from the start [It would be impossible to over-rate the importance of this]

GABUS, J. Organisation et premiers résultats de la Mission ethnographique chez les Touaregs soudanais du 26 décembre 1946 au 10 mars 1947 [Preliminary Report of the Ethnographic Mission to the Tuaregs of the French Sudan in 1946-47] *Acta Tropica* Basle 1948, v 5 No 1, 1-56, 5 maps 11 figs & 16 photos

INDIA **Annual Report of the Public Health Commissioner with the Government of India for 1945** [COTTER, E.] pp iv+91, 2 folding maps & 8 charts 1947 Delhi Manager of Publications [Annas 14 or 1s 3d]

This report is described as being more or less on the same lines as those of the years immediately preceding the war, it contains considerably more information than was provided for the years 1941-1944, but, on the other hand, certain items are omitted because they have already appeared in a preliminary note published earlier in the year (1947).

In spite of the war, some progress can be reported for example, certain provinces introduced compulsory inoculation against cholera for persons desiring to attend the religious "fairs" which had hitherto played so great a part in disseminating infection.

The birth rate for 1945 was 27.3 *per mille* against 25.4 in 1944 and 32 to 34.5 during the five years 1937-1941.

The death rate was 21.5 *per mille* against 24.1 in the previous year and 21.1 to 24.3 during the period 1937-1941. In Orissa the death rate was slightly higher than the birth rate and in the Central Provinces both rates were about 39 *per mille*. In the Punjab the birth rate (about 37) was nearly twice as high as the death rate (19.5).

The infant-mortality rate was 150.9, the lowest ever recorded, but there again there are surprising differences, for example, the rate in the central Provinces was 256.6 whereas in Bihar it was less than 100 although in the latter province the total death rate was nearly the same as for British India as a whole.

It must be understood that all the vital statistics for India are quite unreliable, local checks have repeatedly shown that many births and deaths, especially infant deaths, have not been reported. It is disquieting to find that in a Health Unit in Madras dealing with a population of about 50,000, the infant-mortality rate was 236 despite the fact that for several years the area had been provided with a special health staff, including trained midwives.

In several provinces deaths from cholera and smallpox were more numerous than for many years past but although these diseases attract special attention because of their dramatic nature, taken together they were responsible for only about one-fifteenth of the deaths in British India as a whole. Readers of the report will be surprised at the statement that Bengal was "only mildly" affected by cholera, the deaths from the disease having been 32,550.

Vaccination against cholera was practised on a large scale in most of the affected areas, the numbers of inoculations were in Bengal 7½ million,

in Bihar nearly 6 million in the Central Provinces, Bombay and Madras about 2 million each.

The incidence of plague continued to decline except in Bombay Province where there were 11,779 deaths against 314 in 1944. The preventive value of DDT which was released for use during the year was being investigated.

Malaria was not unusually prevalent during the year. It is interesting to find that "although there is some prejudice in favour of quinine, mepacrine is now becoming quite popular. Fears are expressed that control by DDT may be too costly for general adoption.

As usual the information regarding the prevalence of the enteric group of fevers is meagre, but it is stated as being "fairly certain" that no epidemic occurred during the year. [The most likely explanation of the absence of epidemics in India is that infection is so widespread that most of the children suffer from attacks which are regarded as "simple fever" so that the adult population are relatively immune.]

Pulmonary tuberculosis is believed to cause 500,000 to 800,000 deaths every year but accurate information on the subject is not yet available. Chronic malnutrition is mentioned as one of the chief factors contributing to the prevalence of this as well as of most of the other diseases included under the headings fevers and all other causes which are shown as the causes of about three-fourths of all the deaths that occur in India.

Kala azar is believed to have increased slightly in Bengal and Assam during the year. This is the one disease in India that is being kept under a reasonable degree of control, thanks to the popularity of the effective treatment available in the endemic areas.

A brief summary is given of the important Report of the Health Survey and Development Committee which was completed during the year [see this *Bulletin* 1947 44 25.] Strangely enough no mention is made of the remarkable fact that all but two of the 25 members of this fully representative Committee subscribed to the view that "the growth of population will become an increasingly serious problem and that even if economic productivity is developed to the greatest possible degree "uncontrolled growth of population must as far as we can see outstrip the productive capacity of the country. This view was reached by the Committee after a long and careful study of the available evidence its bearing on the public health policies of all the crowded and backward countries of the world is of crucial importance.

The rest of the present report is on the usual lines: it deals with the work of the official and voluntary health organizations and with medical research which continues to progress far more rapidly than the practical application of the discoveries made by the investigators. The graphs which illustrate the report are very helpful, though necessarily they are no more reliable than the statistics on which they are based.

EAST AFRICAN MED. J. 1948 Jan. v. 5 No. 1 29-73. The Case for the Appointment of a Royal Commission on Health and Population in His Majesty's Dependencies in Africa. Memorandum by the Council of the Kenya Branch of the British Medical Association.

The authors of this long document evidently feel strongly that the time has now come (and is probably overdue) when much more radical and energetic steps must be taken to promote the welfare of the whole population of East

Africa, than have hitherto been considered. They base their argument on the fact that the population is increasing at a rapid rate (some 12 millions in 1936 increasing at a not impossible rate of 2.3 per cent per annum would exceed 18 millions in 1956), and on the other fact that the fertility of the soil is being reduced, largely by inefficient agricultural methods. This problem is by no means peculiar to Africa, and is more and more engaging the attention of medical men and administrators in various parts of the world [see this *Bulletin*, 1945, v 42, 506, 507, 1946, v 43, 81, 603, 1947, v 44, 252, 1948, v 45, 215]. The case made by the authors is very strong indeed, though the reader may think that it would have been even more telling if it had been made much more succinctly.

The memorandum is divided into a prefatory note and two parts. Part I contains the proposal for a Royal Commission, and a discussion of the modern conception of health, which is based very largely on the ideas inherent in the Report of the National Health Services Commission, Union of South Africa, 1944, and on the papers by PATERSON on a population policy for East Africa [see this *Bulletin*, 1948, v 45, 124].

Part II contains a section on planning, in which the authors stress the fact that information on most of the matters relevant to schemes for improvement, is scanty and inaccurate. There is reason to believe that the health of the people of East Africa is deteriorating, and it is known that some parts of the country are so overcrowded that thinning of the population is becoming urgently necessary. The position will probably continue to deteriorate unless a bold effort is made to cope with it. Quotations are given from speeches and reports made by government officials, which support this contention and which show that the position is known in official quarters. The old structure of African society, based on family units and unlimited land, is breaking down in the face of industry, poverty of the soil and crowding.

The health services are inadequate, and must eventually be supported largely by qualified and trained Africans, but in the meantime such medical and public health services as are possible must be developed—but a long-term plan is needed.

The argument for a plan for East Africa is very strong, the suggestion of a Royal Commission may be the best approach to a situation so difficult that it may well be beyond the power of the countries chiefly concerned to deal with it unaided.

Charles Wilcocks

COONOR Pasteur Institute of Southern India, Coonoor. *Annual Report of the Director together with the Fortieth Annual Report of the Central Committee of the Pasteur Institute Association 1946-47* 50 pp, 1 chart 1947 Madras Diocesan Press

The Pasteur Institute of Southern India is a private institution founded in 1906 and governed by a representative committee of its own. While its main object is to provide measures for the prevention of rabies and to undertake research and propaganda in connexion with that disease, it also provides for general laboratory and research work in that part of India. The Institute also gives facilities for research financed from other sources, the Nutrition Research Laboratories of the Indian Research Fund Association has worked there for many years and the Southern India Branch of the Research Section of the Malaria Institute of India worked there during 1946.

Much of the report is naturally devoted to reports and statistical statements regarding rabies and antirabic measures. It is noted that 20,601 patients were treated at the Institute and at Subsidiary Treatment Centres during the year

are met with—careful research and inquiry would probably discover more—in which the primary condition is lepromatous and then, after a long interval, the lesions regress and even disappear leaving scars, and give place to the neuro-cutaneous form secondarily. There were only two such in the authors list. A photograph of one of them is given and photomicrographs to show the histology of sections of the skin.

To sum up the work is a very careful and detailed one might with justice call it a complete study of this aspect of leprosy. There are 109 illustrations all clearly reproduced and showing what the authors describe in the text. The matter is well arranged, the clinical records aptly chosen and quotations fully authenticated. Each chapter has its references in footnotes and these are abundant. In short, this is an admirable piece of work and should be in the hands of all leprologists interested in the clinical and pathological aspects of tuberculoid leprosy. There is no index, but the contents of each chapter are given at the beginning of the book and also at the head of each chapter so that a detailed index is not really needed.

TROPICAL DISEASES BULLETIN

Vol 45]

1948

[No 8

SUMMARY OF RECENT ABSTRACTS*

VII HELMINTHIASIS

Trematodes

Schistosomiasis, general—COWPER (p 217) has written on the maintenance and breeding in Britain of snail hosts of schistosomes, for details the original should be consulted

MUKERJI *et al* (p 599) have been unable to transmit *S haematobium* and *S mansoni*, from African troops, through the common Indian snails

KHALIL and HILMY (p 97) describe a palm-leaf snail trap which is used in Egypt to measure the intensity of snail infestation in water-courses before and after eradication has been attempted. For details the original abstract should be consulted

BARLOW and ABDEL AZIM (p 831), reporting on the control programme in Egypt, make the point that winter closure of irrigation canals causes a high proportion of infected snails to die. Copper sulphate is used, and the authors (p 832) state that there is no advantage in using lime and other chemicals which they have tested. The use of palm-leaf traps in streams lacking vegetation is advantageous. They report considerable reductions in stream infestation as a result of the various measures taken. In experimental work, no infection was achieved with cercariae 48 hours old (compare ALVES below)

Gammexane is lethal to *Bulinus* and *Planorbis* in Egypt in concentrations of 5–6 p p m acting for 24 hours. HALAWANI (p 331) thinks that much smaller doses would suffice if applied for a longer time. The same author (p 667) claims that the *delta* isomer of benzene hexachloride is effective against *Bulinus* and *Planorbis* in a dilution of 5 parts per million

Schistosoma haematobium—STEPHENSON (p 598) describes the schistosomiasis position in the Gezira area of the Sudan, where the land is irrigated from the great dam at Sennar. There are 2,600 miles of irrigation channels, some of which are used only by day, others throughout the 24 hours. There has apparently been a great increase in the infestation rate with *S haematobium*, and 21 per cent of adults and 45 per cent of children are infested. *S mansoni* is present in 5 per cent in some places, but no one method of stool examination will reveal all cases. The position seems to be deteriorating, and treatment

* The information from which this series of summaries has been compiled is given in the abstracts which have appeared in the *Tropical Diseases Bulletin* 1947 v 44. References to the abstracts are given under the names of the authors quoted and the pages on which the abstracts are printed

campaigns, construction of latrines, siting of villages away from canals, and propaganda have not succeeded in controlling the disease. Snail-clearance as practised in Egypt, is needed.

BUCKLEY (p. 909) has made a survey of N Rhodesia in which he found *S. haematobium* infection in up to 60 per cent. of the people children showing higher figures than adults. *Physopsis globosa* and *P. africana* are the snail hosts they are essentially inhabitants of small streams, and are scarce in large rivers lakes or swamps.

MAKAR (p. 1010) writes on the pathology and treatment of carcinoma of the bladder in Egypt which is probably associated aetiologically with *S. haematobium* infection. Other papers on schistosomiasis and cancer have been written by SCANDER BEY (p. 1010) OXSY BEY (p. 1011) and MAKAR and FAWRY (p. 1011).

ALVES and BLAIR (p. 828) describe the preparation of an antigen from cercariae of *S. haematobium*. This is used for the intradermal test and is valid for *S. haematobium* or *S. mansoni* infections. In a large series of persons tested, there were no negative results in those excreting eggs, and eggs were found in a large proportion (increasing as examinations were repeated) of those with positive tests to this antigen. The authors therefore consider the test to be accurate enough for diagnostic use in mass treatment campaigns in S. Rhodesia, where the intensive treatment with sodium antimonyl tartrate is practised. Negative reactors are probably free from the disease.

A description of the field work done during 1948 in S. Rhodesia is given by ALVES and BLAIR (p. 827) who by the intradermal test referred to above have found infection in 4-41 per cent. of Europeans and 13-89 per cent. of Africans. They treated 5455 infected persons by intensive courses of sodium antimonyl tartrate (total dose 1 grain to 20 lb body weight divided into 3 parts and injected in very dilute solution and very slowly at intervals of 3 hours). There were no deaths from the drug, but the technique of administration is of the greatest importance. For snail control they used copper sulphate, of which a concentration of 5 p.p.m. kills all snails in 4 hours in the laboratory it is much more effective than malachite. The control work should be done in the dry season in S. Rhodesia.

ALVES (p. 829) reports that GORMAN has discovered that schistosome cercariae may live as long as 144 hours in cold weather and be infective for fish. The old idea that by storing water for 48 hours, free from snails, it is rendered harmless for schistosomiasis cannot now be accepted.

SKITZ (p. 829) has treated 322 patients, mostly with *S. haematobium* infection, by an intensive method similar to that used by Alves and Blair without serious reaction, and with good results.

BARTER *et al* (p. 1012) show that blood levels of tartar emetic fall very rapidly and that excretion by urine (80 per cent.) and faeces (20 per cent.) is rapid. Experience with multiple injections suggests that it is possible to maintain a higher blood level by controlling the size and frequency of doses.

HALAWANI and ABDALLAH (p. 220) gave Repodral (an American preparation identical with Fouadin) 3 times a day for 2 days to Egyptian patients with *S. haematobium* infections, with some success. The total dose was 0.5 cc. (of 0.3 per cent. solution) per kgm. divided into 3 parts. This intensive treatment is probably safer than the intensive treatment with tartar emetic in view of the prevalence of balharzial cutaneous and nutritional deficiencies in Egypt. (The Repodral was presumably given by intramuscular injection, but this is not made clear by the authors. HAMMOUDA (p. 221) examined the hearts of these patients by electrocardiography but any changes found were slight and transient. HALAWANI and HALL (p. 329) prepare a 0.5 per cent. solution of Repodral solution immediately before use. This solution should be used on the day of preparation. Toxic symptoms are generally mild. EL AWADI

(p 433) shows that after an intensive two-day course of Reprodral (Fouadin, Stibophen), much of the antimony was concentrated in the liver. A cumulative effect was clearly demonstrated. GELLHORN *et al* (p 334) discuss the tissue distribution and excretion of certain organic antimonials in hamsters, for details the original should be consulted.

RITCHKEN and KANTOR (p 1078) report a few cases of herpes zoster in patients treated by the intensive course of intravenous antimony injections, they discuss its aetiology.

WOOD (p 914) reports on the pharmacology of Miracid, the new drug which is claimed to be active against schistosomes.

S. mansoni—In N Rhodesia BUCKLEY (p 909) found *S. mansoni* in up to 61 per cent of people. In general the areas of high incidence with *S. mansoni* were not those with high incidence of *S. haematobium*, and children were not specially affected. It was common to find eggs in faeces without blood or mucus, and the disease appears to be very insidious. The snail host is probably *Biomphalaria pfeifferi*, evidence regarding the closely allied *B. tetragonostoma* is inconclusive. These snails are found in small streams, but are scarce in lakes and swamps.

SCHWETZ (p 1009) found that about 10 per cent of 317 persons examined along the Bushumale river in the Belgian Congo had intestinal schistosomiasis, and found *Planorbis adowensis* and *Bulinus forskali* in the neighbourhood.

SCHWETZ and DARTEVELLE (p 825 bis) discuss the snail hosts of *S. mansoni* in the eastern part of the Belgian Congo, and give some information on their ecology. [In the original abstracts *Planorbis boissyi* *tanganikanus* was misspelt *tanganikus*].

RODRIGUEZ-MOLINA and SCHWACHMAN (p 829) found *S. mansoni* in 14.6 per cent of a large number of recruits in Porto Rico. They treated a number with Fouadin, but the end results after 24 months were not good—more than half the men still excreted eggs, though some of them had had as many as 6 courses of the drug. PONCE PINEDO (p 826) reports the first known autochthonous cases of *S. mansoni* infection in the Republic of Santo Domingo.

LUTTERMOSER (p 1078) has contributed a comprehensive account of schistosomiasis in Venezuela, where the disease is well established in certain States. The snail host is *Australorbis glabratus*, and in the programme of control, treatment, drainage of land, application of lime and other chemicals to kill snails and the development of good methods of disposal of faeces are prominent features.

JAFFÉ and FERRO (p 433) discuss the diagnosis of schistosomiasis in post mortem material in Venezuela, comparing different techniques for the demonstration of ova in liver and rectum. By various means they obtained positive results in 34 of 86 cadavers.

S. mansoni infection is very widespread in Brazil, PINTO and DE ALMEIDA (p 96) give a list of 198 foci already found, chiefly in the State of Pernambuco. CANÇADO (p 912) reports on the distribution of *S. mansoni* in the State of Minas Geraes, Brazil.

PINTO (p 216) relates a focus of *S. mansoni* infection near Rio de Janeiro to watercress gardens contaminated with human faeces and harbouring *Australorbis glabratus*. PINTO and DE ALMEIDA (p 216) give a list of other occupations which carry special risk—washerwomen, workmen building bridges, engineers, topographers, fishermen, and persons, young and old, who break down the *guaxima* tree for fibre, standing in water to do so. The snail hosts in Brazil are *A. glabratus* and *A. olivaceus*.

CRAM and FILES (p 217) have confirmed previous findings that a species of *Tropicorbis* found in Louisiana is capable of acting as host for *S. mansoni*, various other species tested could not be incriminated. In an investigation of

a number of species of snails found in the Eastern United States, while STUNKARD (p. 432) attempted to infect with the three human schistosomes, no evidence was found that any could act as an intermediate host for any of the trematodes.

Snails normally liberate cercariae once each day around midday but KUN (p. 330) has been able to force *A. glabratus* to shed cercariae of *S. mansoni* more often, by exposing them to various intensities and periods of light, and to different temperatures. Abrupt changes in temperature exert more influence than abrupt changes in light intensity.

HASHEM (p. 730) discusses Egyptian hepato-splenomegaly which is endemic in an area roughly corresponding to that of *S. mansoni* infection. In all cases at post mortem, in which eggs could be differentiated in the liver they were eggs of *S. mansoni* and this trematode is the cause of the condition four times as often as *S. haematobium*. In schistosomal cirrhosis the fibrosis is essentially interstitial, and is due to infiltration in and around the fine portal tracts by eggs or even adult worms. ERFAH (p. 913) describes the pathology of the liver in schistosomiasis in Egypt eggs of *S. mansoni* are found more than 4 times as often as eggs of *S. haematobium* in hepatic schistosomiasis. He also describes the symptoms of these infections and the course they take. For details the original should be consulted.

HALAWANI *et al.* (p. 99) show that in long standing intestinal schistosomiasis with liver changes and enlarged spleen, the cephalin flocculation test and the colloidal gold test are often positive.

IGNACIO BALDO *et al.* (p. 1077) have examined by X-ray the lungs of a number of children infected with *S. mansoni*. Changes were found in about half, but seem to have been somewhat indefinite. There was evidence of myocarditis, with enlargement of the heart in some.

WELLER and DANDON (p. 98) use a wetting agent (Triton NE) with the acid-ether centrifugation technique, for the examination of faeces for eggs of *S. mansoni*. By this means they found eggs in 105 of 500 specimens without the wetting agent only 84 gave positive results. OLIVER-GONZÁLEZ and HERNÁNDEZ MORALES (p. 830) describe their method of examination of faeces for eggs of *S. mansoni* by a sedimentation technique which enables them to distinguish microscopically between living and dead eggs by observing the movements of the flame cells. They have applied this to patients after treatment with anthiomaline or urea stibamine the simultaneous disappearance of living and dead eggs suggests that dead eggs are either laid dead or die in transit from the place where they are laid. Dead eggs found in faeces are not necessarily eggs which have been a long time in the mucosa.

HERNÁNDEZ MORALES *et al.* (p. 300) find rectal biopsy much more accurate for the diagnosis of *S. mansoni* infections than either concentration methods of stool examinations, or antigenic skin tests. WELLER (p. 599) has designed a rectal scraper which, although not so effective for the diagnosis of *S. mansoni* infection as the acid-ether concentration method, may be a useful complement.

CLEBERTSON *et al.* (p. 912) show that extracts of cercariae of *S. mansoni* and of two other worms (not parasitic in man) possess a common antigen which can be used for skin tests in schistosomiasis and other trematode infections. PRATT and OLIVER-GONZÁLEZ (p. 826) show that antigens prepared from cercariae of *S. mansoni* do not lose potency for intradermal tests if stored at 8°C. for 12 months. GOLDSTEIN (p. 328) describes an antigen he prepared by extracting adult *S. bovis* in saline. He has used this as an intradermal test for intestinal schistosomiasis. It is apparently useful, but the series tested was very small.

LÓPEZ (p. 914) regards palpable thickening of the sigmoid colon as a useful diagnostic sign of *S. mansoni* infection.

HERNÁNDEZ MORALES *et al* (p 731) find tartar emetic more effective than Fouadin in the treatment of *S. mansoni* infections, provided that 1 per cent solution is given intravenously in doses of 5 cc to a total of at least 120 cc, the injections being given on alternate days. A second course may be necessary.

HERNÁNDEZ MORALES *et al* (p 218) have used Anthiomaline in the treatment of *S. mansoni* infections in Porto Rico. Given by intramuscular injection in doses of 3 cc (± 10 mgm antimony) on alternate days, to a total dosage of 45-48 cc, it rarely produces serious toxic reactions, and appears to be quite effective against the infection.

For the refractory proctitis often left after treatment of intestinal schistosomiasis, RADNA (p 99) has used histidine injections with success.

BRANDT (p 667) has found that adult *S. mansoni* can be removed from the portal vein of heparinized rabbits more easily than from non-heparinized rabbits, and suggests that heparin can be given to mobilize the worms, followed by introduction of an anthelmintic into the portal vein at operation.

KUNTZ and STIREWALT (p 434) have tested DDT against cercariae of *S. mansoni*. Its cercaricidal power is so slight, even under laboratory conditions, that it is not an effective agent for control of schistosomiasis.

JONES and BRADY (p 217) show that a (model) diatomaceous silica water filter was effective in preventing the passage of cercariae of *S. mansoni* in the Philippine Islands has been written by BANG and his colleagues (p 435). They make the startling remark that it is possible for half the population to be infected and yet for the infection to be unrecognized by the local physicians.

In their surveys they used a sedimentation technique for examination of faeces, and they claim that if this method [or presumably some other concentration method] is not used, a large proportion of infections will be overlooked. In hyperendemic areas 80 per cent of children have enlarged livers, and the liver index is a useful guide to the prevalence of the disease. In Leyte, buffaloes and young pigs, and elsewhere rats, have been found infected. The only known snail host in the Philippines is *Oncomelania quadrasi*. American troops were infected in the course of engineering work associated with water, or while swimming or washing. For experimental work, guinea-pigs were found most suitable, and in therapeutic tests the efficacy of tartar emetic, Fouadin and anthiomaline was confirmed. Applications of benzyl benzoate or dimethyl phthalate to the skin affords some protection, and certain clothing materials commonly used in the U.S. army prevent penetration by cercariae, especially if the garments have been treated with benzyl benzoate, dibutyl phthalate, or a mixture of these.

WRIGHT *et al* (p 832) report on surveys made for schistosomiasis on Mindanao. *O. quadrasi* is present in 11 districts of Szechwan, China, a province formerly regarded as relatively free. Kuo (p 331) indicates that *Schistosoma japonicum* has been found in some areas.

VOGEL (p 330) has crossed *S. japonicum* with *S. mansoni* and a few of the resulting eggs produced embryos which developed in snails. The offspring resemble the female parent, and it is not certain that the process of reproduction is not one of parthenogenesis or pseudogamy.

The snail host of *S. japonicum* in the Philippines is *Oncomelania quadrasi*. McMULLEN (p 917) shows that this snail is amphibious and operculated, that it lives under varied conditions in scattered colonies, and that the main foci in which these snails come into contact with man are rice plots which have been abandoned for a time. He has observed the growth of these snails, their life-span is at least one year and they may be infected shortly after hatching.

McMULLEN and GRAHAM (p. 917) think that under war conditions, impregnated clothing and protective ointments offer considerable protection against cercariae of *S. japonicum* but because no cercaricidal substance has yet been found effective in large bodies of water practical control entails elimination of the snail host (*O. quadrasi*). Chemicals are best used against this amphibious species in the dry season. The authors tested 19 chemicals on plots of ground—they were effective in killing the snails in different concentrations, but all except two dinitro compounds injured the vegetation. Drainage and removal of the taller vegetation are also needed for the best results.

McMULLEN and INGALLS (p. 917) tested 10 chemicals against cercariae of *S. japonicum*. These had also been used in tests against *O. quadrasi*. Details should be sought in the original.

INGALLS (p. 447) has studied the action of salt water on the cercariae of *S. japonicum*. Sea water with 3 per cent. salt is lethal to cercariae within 3 minutes, but 1.5 per cent. is not and such water is potentially dangerous to man, for instance where sea water is diluted by river water.

FAUST (p. 833) shows that eggs of *S. japonicum* (from the Philippines) may remain viable in the cold (at 4°C.) for 27 days if stored without washing and up to 6 months if stored after washing. Winter temperatures in China and Japan are too low for hatching.

FAUST and INGALLS (p. 331) discuss the various techniques that have been used for examination of faeces for eggs of *S. japonicum*. They make the point that the zinc sulphate centrifugal floatation method is not satisfactory because only a small proportion of the eggs will float. Direct smear is useful, but sedimentation after homogenization in 0.5 per cent. glycerin in water, ether centrifugation, and the technique in which sodium sulphate solution, a detergent and ether are used, with centrifugation, produce better results. The subject is discussed in detail and readers should consult the original. HUXTER *et al* (p. 440) also write in favour of the last method.

BARBOODY and MOSE (p. 333) find that if faeces are diluted with water and centrifuged, several times, examination of the sediment for eggs of *S. japonicum* gives more positive results than direct smear and than the ether-zinc sulphate or brine floatation methods. This method has the additional advantage that it is simple.

HOLLANDS and PALMER (p. 439) have found that aspiration of the rectal crypts (even if normal in appearance) or scraping and aspiration of suspected lesions, is a valuable means of diagnosis of *S. japonicum* infection when faeces are negative. Aspiration is carried out with a motor-driven suction pump and a glass pipette which are described.

An antigen consisting of a saline extract of cercariae of *S. mansoni* is not species-specific (though it shows a high degree of specificity for trematodes) and HATZEL and MOSE (p. 440) have used it with success in an intradermal test for the diagnosis of *S. japonicum* infections. The tests became negative within 8 months in many persons who received Fouadin treatment—they therefore have a value for prognosis.

WRIGHT *et al* (p. 833) prepared antigens from adult *S. mansoni* for use in intradermal and flocculation tests for *S. japonicum* infection. The intradermal test gave somewhat disappointing results, especially in early cases, and only 83.7 per cent. of 104 persons microscopically diagnosed gave positive results with the flocculation test. Some non-specific reactions were observed.

WILLIAMS (p. 399) shows that a complement-fixation test, with an antigen-prepared from livers of *Planorbis eximius* heavily infected with *S. japonicum*, is outstandingly effective for the diagnosis of *S. japonicum* infections. The test is more sensitive and less tedious than repeated examination of the stools for ova.

She quotes the results, in 560 men examined, on which she bases her conclusions. DAKIN and CONNELLAN (p 915) give an account of the outbreak referred to by Williams above, and report the same tests, but they also describe the symptoms, and the results of treatment with Fouadin, which were poor.

WINKENWERDER *et al* (p 834) report on 364 cases of *S japonicum* infection in United States troops in the Philippines. The incubation period was from 26 to 58 days, and ova were found about one month after the onset of symptoms. Eosinophilia, often to 85 per cent of the total leucocytes, was a common finding. Yellowish nodules were observed in the intestinal mucosa on sigmoidoscopic examination, and these were regarded as evidence of relapse after treatment. Fouadin, tartar emetic and anthiomaline were used in treatment, the relapse rate with Fouadin was about 40 per cent. MARTIN *et al* (p 334) note that a story of prolonged fever with urticaria, weakness, diarrhoea and other abdominal symptoms was the most significant clinical finding in American soldiers infected with *S japonicum*.

LEAVITT and BECK (p 916) make the point that *S japonicum* infection was asymptomatic in a considerable number of members of an American hospital staff in the Philippine Islands. Diagnosis was made by examination of faeces and the recognition of small lesions (stellate distended venules, sometimes with a central pustule or ulcer) in the recto-sigmoid mucosa. Eggs were found in scrapings from these lesions.

MASON *et al* (p 732) report on American soldiers admitted to hospital some 6 months after the onset of acute symptoms of schistosomiasis. Early symptoms included fever and abdominal pain, sometimes with diarrhoea and palpable liver, rarely with urticaria and palpable spleen. Eosinophilia over 9 per cent was common. Diagnosis during the later stage, by finding *S japonicum* in the faeces, was rarely positive at the first attempt, and sometimes needed 10 or more examinations. Lesions detectable on proctoscopy were very rare. Eight of 481 patients showed neurological symptoms and two who were accidentally killed showed military abscesses in the liver. Treatment with potassium antimony tartrate (0.5 per cent) gave better results than treatment with Fouadin.

TILLMAN (p 600) discusses cerebral involvement in *S japonicum* infection and reports 7 cases in which this diagnosis was made on clinical grounds. The symptoms are described, none of the patients (American soldiers) died, but treatment with antimony was only partly successful. WATSON *et al* (p 916) describe a case of cerebral involvement in *S japonicum* infection, lesions in the brain were recognized at operation, the patient having had convulsive seizures, and localizing signs being present. CUTLER (p 1079) also describes a case of *S japonicum* infection in which the central nervous system was involved, treatment with Fouadin was very beneficial and the author advocates it, as early as possible.

Two cases of acute pulmonary lesions due to *S japonicum* are described by WEINBERG and TILLINGHAST (p 441), the radiographic appearances suggested military tuberculosis due, in one fatal case, to pseudo-tubercles which had formed around schistosome eggs. Cough, pain and scattered râles were present.

LIPPINCOTT *et al* (p 601), having made tests of liver function in *S japonicum* infection, conclude that antimony treatment has a minor effect on the liver.

Other trematodes—BERTRAND (p 1080) reports a case of paragonimiasis from the Belgian Congo. FEDERICO HEINERT (p 1080) reports 26 cases of paragonimiasis from Ecaudor, discovered during the last 25 years. Most of the patients were cured by emetine.

DE OLIVEIRA and MEIRA (p. 168) diagnosed *Clonorchis sinensis* by examination of bile obtained by duodenal drainage in a man born in Shanghai, who lived in Brazil.

FRIESS (p. 442) describes three cases of infestation with *Fasciola hepatica* in one family in Algeria. Infection was probably acquired from watercress. Only one showed symptoms—loss of weight, slight fever, anorexia, anaemia and eosinophilia.

BOXER *et al.* (p. 1013) describe a new echinostome parasite of man in Java, *Echinostoma reomanum*, and discuss the probable snail hosts.

In Oregon, MACFARLANE and MACY (p. 97) describe a new species of cercaria (*C. oregonensis*) which causes swimmers' itch. The host snail is *Physa ampulacea*. The authors observed that the cercariae seemed to penetrate the skin as the water containing them evaporated. The dermatitis lasted from 1 to 4 w. els.

Cestodes

In a study of the life-cycle of *Diphyllbothrium manson* in Tonkin, GALLIARD and NGU (p. 733) have found that three intermediate hosts (instead of two) are apparently necessary. The cycle is dog-*Cyclops* tadpole-frog. Experiments to infect frogs by feeding them on infected *Cyclops* failed, but tadpoles could be so infected, and frogs could be infected by ingesting infected tadpoles. The authors therefore regard tadpoles as essential intermediate hosts.

A human case of sparganosis (undifferentiated) was reported, for the first time in the Belgian Congo, by FAIX (p. 1080).

Evidence is produced by VON BONDORFF (p. 1081) that pernicious tapeworm anaemia (*Diphyllbothrium latum*) is due to interference by the worm with the interaction between intrinsic and extrinsic factors. The site of this interaction is probably the intestinal wall.

DICKMAN (p. 221) describes four cases of cysticercoosis of the posterior cranial fossa.

NEGEMÉ and FAIGUENBAUM (p. 734) have treated various forms of taeniasis with quinacrine apparently with success.

A method for biological estimation of substances used in treating cestode infestations is described by HOLTON (p. 835).

VAN AMERONGEN (p. 734) notes that *Echinococcus granulosus* infection is common in dogs in the Dutch province of Gelderland, especially on farms where slaughter regulations are lax.

DUXDAL (p. 100) discusses the great reduction which has been made in the incidence of human hydatid disease in Iceland, where it was once very common. The decrease is ascribed largely to education of the people and to anthelmintic treatment of dogs each year.

In Egypt, EL KORDY (p. 601) shows that hydatid disease is common in camels (31 per cent.), buffaloes (16), cattle (16) and sheep (1.5 per cent.).

COLE (p. 602) describes the Australasian Hydatid Register with 1,842 cases, almost equally from Australia and New Zealand. Most of the cysts were in the liver.

BRISOU (p. 222) has used, for the diagnosis of hydatid disease, extract of tapeworms of different species with which he performs intradermal tests. The active substance is a polysaccharide fraction joined to a distinct protein fraction, and it is about as specific as the antigen obtained from hydatid fluid. It is necessary to know if the patient has had tapeworm infestation previously. Details of preparation are given.

WATSON (p. 222) confirms a previous finding by STICKARD that *Hymenolepis nana* is found in Syrian hamsters but his investigations do not indicate that there is much danger of infestation of laboratory attendants who handle them.

HARANT *et al* (p 1013) found *Hymenolepis nana* in a child suffering from persistent diarrhoea, in Montpellier. Three other children in the same family were also found to be infected, and the authors report that almost half the population had suffered from persistent enterocolitis during the same summer. Infection had presumably been introduced by French African troops stationed there.

RABIES

JACOTOT, H. L'addition de latex d'*Hevea brasiliensis* au vaccin antirabique formolé en vue d'augmenter son activité [The Addition of the Latex of *Hevea brasiliensis* to Formolized Antirabic Vaccine as a means of increasing its Activity] *Ann Inst Pasteur* 1948, Jan, v 74, No 1, 53-4

The addition of a small amount of the latex of *Hevea brasiliensis* to antirabic vaccine prepared from formalized brain pulp increases appreciably the activity of the vaccine. Results of experiments described indicate that only 9 of 57 guinea-pigs which received the vaccine containing the latex succumbed to the virulence test, compared with 34 out of 57 which received the vaccine without latex. In other words 84 per cent of the first group, but only 40 per cent of the second were protected. All of 19 non-vaccinated control guinea-pigs died.

These results are similar to those obtained when alumina gel was used as an adjuvant [see this *Bulletin*, 1948, v 45, 291] H J O'D Burke-Gaffney

EMLINGER, P & BAILLY, J. L'extension des vaccins antirabiques phéniques et la nécessité d'une Conférence internationale de la rage [The Increasing Use of Phenolized Vaccines in Anti-Rabies Treatment and the Need for an International Conference on Rabies] *Bull Acad Nat Méd* 1948, v 132, Nos 9/10, 166-8

In this paper communicated to the National Academy of Medicine in Paris at its meeting on 9th March, 1948, the authors again advance arguments in favour of the general adoption of phenolized killed virus vaccine for use in anti-rabies treatment.

Moreover they make a strong plea, based on the experience of French North African territories and elsewhere, not only for canine prophylaxis but also for the curative treatment of dogs and other domestic animals bitten by rabid animals.

In this connexion surprise is expressed that, by failure to recognize the greater utilitarian value of phenolized vaccines and the need for the vaccination of animals other than man, France has not kept abreast with modern ideas on anti-rabies treatment.

With a view, therefore, to having the whole subject of anti-rabies treatment reviewed and, if possible, uniformity of procedure reached, the authors urge the early calling of an international rabies conference, similar to that held in Paris in 1927. Items on the suggested agenda include the nature of rabies virus, its culture, the influence of passage on the susceptibility of fixed virus to the action of attenuating agents, "rage de laboratoire" and paralytic accidents, rabies in the wolf and the intensive treatment necessary in the case of wolf bites, "failures" of treatment, criticism, particularly from the United States, of anti-rabies vaccination.

[The paper under review recapitulates the views expressed on anti-rabies treatment by the authors in their recent handbook *La Rage* see this *Bulletin* 1948 v 45 387]

MALARIA

SAUTET J. A propos de la régression spontanée " du paludisme. ["Spontaneous" Regression of Malaria.] *Bull. Soc. Path. Exot.* 1943, v 41 Nos. 1/2, 31-3.

As a result of observations in Corsica, the author in 1933 put forward the hypothesis that the so-called "spontaneous" epidemiological regression of malaria might be due to a limited tendency for the parasite concerned to form gametocytes, so that mosquitoes had less chance of becoming infected.

He now refers to an epidemic of malaria in Camargue in 1943 where endemicity of malaria is normally very low. In this outbreak, he was struck by the absence of gametocytes in the blood of those infected with the strain of *P. vivax*. This epidemic soon waned, giving place to the previously low endemicity.

These results contrasted strikingly with those found in intensely malarious areas in Corsica, where he had noted a gametocyte index of 28.3 per cent. or in the Lebanon where an index of 20 per cent. was found among Armenian refugees.

He refers to the results of SERGIEV and TIBURSHAYA [this *Bulletin* 1945 v 42, 822] who found that a strain of *P. vivax* from a southern region of the U.S.S.R. showed a greater tendency to produce gametocytes than did a strain from a northern region.

The author concludes that these findings support his thesis that the epidemiological regression of malaria is largely due to the limited capacity of the responsible strain to produce gametocytes. H. J. O. D. Burke-Gaffney

DORLEMAN H. & VAN TRIEL, P. H. De malaria-epidemie te Middelburg in de jaren 1940 tot en met 1945 benevens een onderzoek van parasieten dragers. [The Malaria Epidemic at Middelburg 1940-1945 and Parasite-Carriers.] *Nederl. Tijdschr. v. Geneesk.* 1948, May 1 v 92 (ii) No. 18, 131-18. English summary (9 lines)

The report on this epidemic was given in full by DORLEMAN [this *Bulletin*, 1948, v 43, 875] as a doctorate thesis. He concentrated attention on the parasite carrier especially the healthy carrier who makes little complaint of sickness, has a normal blood count and differential count and no alteration of his sedimentation rate. A few carriers showed lymphocytosis but there was no indication of monocyte increase. These parasite-carriers were treated and 65 of them were very strictly under observation for at least a year. None of them had a relapse either in the year or in the following year showing that they still had the advantage of premunition. Confirmation was obtained of the assertion that the variation in the number of parasites was periodic: 10 to 16 days of a positive phase and 8 to 14 days of a negative phase. This was an important observation for the control of a parasite carrier. It was not necessary to examine the blood daily but only 10 days and 16 days respectively after the previous examination.

That epidemic malaria occurred in Middelburg and nowhere else in Zeeland is explainable by (1) the presence of parasite carriers (2) the incursion of parasite carriers and (3) conditions satisfactory for the maintenance of anophelines. The first of these explanations is the same as to state that

malaria is endemic in Middleburg the second refers to the occupation of barracks by Germans, and the third to the presence of military horses in the centre of the town, so that more anophelines were attracted there than in normal years

Now that Zeeland and Walcheren have been freed of malaria, responsibility that they shall continue to be free belongs to the medical practitioner. He should report all cases of malaria, see that blood examinations are carried out and go carefully into the question whether the case is autochthonous

W. F. Harvey

GARACI, C. L'andamento dell'infezione estivo-autunnale in Cassino [The Course of *P. falciparum* Infections in Cassino] *Riv di Malarologia* 1947, Dec., v. 26, No 6, 283-95, 4 charts [16 refs.] English summary

The communes in the neighbourhood of Cassino were not malarious before the war, but after the destruction wrought by war in 1943 malaria became both prevalent and severe. The disease was widespread in 1944. *P. vivax* infections were most in evidence and only a few *P. falciparum* infections were identified. In the following year, however, *P. falciparum* became widely diffused and there were many fatalities. In July 1945, the Rome Institute of Malariology opened a diagnostic centre in Cassino and the results of some of their investigations are summarized in this report.

During the last six months of 1945, 2,312 blood samples were examined of which 58 per cent were positive for malaria. Of positive findings, 60.5 per cent were *P. vivax* and 39.5 per cent *P. falciparum*. In 1946, of 3,124 bloods examined, 66 per cent were positive, *P. vivax* 86.1 per cent, *P. falciparum* 13.9 per cent.

P. falciparum infections rose in July and increases followed in August and September. The decline in the incidence curve commenced in October. In Central and South Italy, as a rule, the *P. falciparum* incidence curve rises steeply in July and August and thereafter declines almost as steeply. The July rise is hard to explain. In June, gametocyte carriers were very few, the mean temperature was only about 21°C, at which temperature the extrinsic cycle of development of *P. falciparum* is of about a month's duration. It is hardly likely that the early cases were relapses of infections contracted in the previous year.

HEISCH, R. B. A Parasitological Survey of Taveta. *East African Med J* 1948, Feb., v. 25, No 2, 78-94, 5 figs

This paper is a continuation of the author's parasitological surveys in Kenya Colony [this *Bulletin*, 1947, v. 44, 678] and refers to conditions in the small Taveta reserve, close to Kilimanjaro. Future workers will undoubtedly find these records of great value, surveys in new countries today are so often handicapped by having no historical background. Also, a widespread sampling of the population and its environment is always likely to reveal something of immediate interest, and here the author has discovered a condition of splenomegaly which cannot be ascribed to any of the ordinary causes. The spleen rate of one group of adults living near Lake Jipe was 58 per cent while the malaria parasite rate was only 18 per cent, a peculiar relationship for inhabitants exposed to hyperendemic malaria, where both rates should be low. This group showed, in addition, an 11 per cent infection rate with the ova of *Schistosoma mansoni* on single stool examinations and it is suggested that the high adult spleen rate may be due partly to the presence of this helminth.

Miss., and *sicantii* Roob. and *A. sacharovi* Fabr. The geographical distribution of the three species is shown on a map, and a new specific group within the subgenus *Anopheles* named *Mical pernix* is erected for them. The diagnostic characters of this group are described, and characters are given in a table distinguishing the three species in the egg, larval and adult stages (these last consisting mainly of differences in the male hypopygia) with notes on habits. A list of the Italian Anophelinae is included.

YOCKE M. D., HARDMAN N. F., BURGESS, R. W., FROMME W. C. & SABBOSKY C. W. The Infectivity of Native Malaria in South Carolina to *Anopheles quadrimaculatus*. *Amer J Trop Med.* 1948, Mar., v 28, No. 2, 303-11 1 fig.

The susceptibility of anopheline mosquitoes to infection with the different species of malaria parasites has usually been worked out in the laboratory by means of artificial infections. In this investigation, natural infections were used and their infectiveness to the local anophelines (*A. quadrimaculatus*) was determined. The patients were negroes living in South Carolina and were known to have had malaria within recent months. A hundred mosquitoes were fed on each patient irrespective of whether his blood contained gametocytes or not or even parasites of any sort. 14,811 mosquitoes were fed in 185 lots. 142 lots were fed upon *P. falciparum* patients. 14 lots on *P. malariae* and 9 on *P. vivax*. The last were all negative (in fact at the time of feeding, only one case showed parasites and these were all asexual). The *P. malariae* cases showed gametocytes in four instances and three of them infected the mosquitoes. Twenty five patients out of the 14 *P. falciparum* cases showed gametocytes, all in low density and 16 of these infected mosquitoes. Some of the patients showed neither sexual nor asexual parasites at the time of feeding, and yet four of these cases were infective to mosquitoes. The patients without symptoms were just as efficient carriers as those with symptoms. The whole trend of these experiments shows that gametocyte density can be extremely low and yet mosquitoes can become infected under such conditions. The majority of the infections resulted from feeds on people showing fewer than 10 crescents per cmm. of blood. One patient with a *P. falciparum* infection was able to infect mosquitoes throughout a period of eight months. The duration of this species of infection appeared to approach a year but further work is progressing to determine the exact duration. P. C. C. Garnham

WILLIS, E. R. The Olfactory Responses of Female Mosquitoes. *J. Econom. Entom.* 1947 Dec., v 40 No. 6, 769-78, 2 figs. [13 refs.]

Anopheles quadrimaculatus and *Aedes aegypti* were used in a series of experiments in an attempt to observe and record their olfactory responses. Most of this paper consists of a description of the olfactometer and the experimental technique and is not easily summarised.

A diagram is given of the apparatus through which two streams of air are passed, either could carry an odour while the other served as a control. Light, temperature, humidity and other factors are regulated.

For each test, 50 female mosquitoes of known age were placed in a wire cage with a glass front, into which the two air streams arrived. Photographic records were made of the mosquitoes' movements at intervals of one minute for a test period of ten minutes. Counts were made on the developed films, which showed the numbers and distribution of the insects.

Data are presented which show that non-blood-fed females of both species were attracted by the odour of the human arm when the air was at 34°C and

between 70 and 85 per cent relative humidity. Blood-fed females of *Aedes aegypti* and males are not attracted to arm odour. There was no indication that carbon dioxide in 1, 10 or 50 per cent concentrations was attractive to either species [See also this *Bulletin* 1947, v 44, 787].

ROSENSTIEL, R G. **Dispersion and Feeding Habits of *Anopheles freeborni***
J Econom Entom 1947, Dec, v 40, No 6, 795-800, 3 figs [13 refs]

One method of studying anopheline dispersion from breeding places is by marking, releasing and recovering female mosquitoes. Another is by measuring population fluctuations at successive distances from the breeding places. The latter method (adopted by the author) can only be used where breeding places are isolated. Two such breeding places were found in the Sacramento Valley. One is referred to in this paper as the Dixon-Suisun area and the other as the Yuba City area.

The adult haunts chosen for study were those where *Anopheles freeborni* had been found the previous year. They were barns, basements, sheds, bridges and culverts which were situated at varying distances from the breeding places at intervals of a mile or two. They were visited once a week when mosquitoes were collected, counted and examined for eggs, fat body and species, then carefully returned alive to their resting places.

The two areas were divided into zones and the data recorded on charts. From these it is observed that no dispersal occurred until mid-July. Then there was a congregation of adults around the breeding places which went on until some time in the last three weeks in August, during which time the females were feeding. The numbers then declined about the breeding places and increased in the resting places up to five miles away where there were no areas for breeding. During September and October dispersal was very active and was most noticeable within ten miles of the breeding places.

Adults from the Yuba area were found at least 4-5 miles to the south and some from the Dixon-Suisun area travelled at least 26 miles. Feeding went on during the dispersal and females contained eggs, hibernating ones contained fat and those which managed to survive the winter were seen to contain eggs, fat or blood in the following February.

SILVA, W. **Contribuição ao estudo da história da malária na cidade do Salvador—Bahia [A Contribution to the Study of the History of Malaria in the City of Salvador, Bahia]** *Rev Med-Cirurg Brasil* 1945, v 53, Nos 2/3, 17-59, 5 graphs & 1 diagram [56 refs] [Summary taken from *Rev Applied Entom* Ser B 1948 Mar, v 36, Pt 3, 51-2].
H S Leeson

The author outlines the history and geography of Salvador the capital of the State of Bahia, Brazil, in which malaria has been endemic and occasionally epidemic, since it was first built. In 1929, *Anopheles argyritarsis*, R-D, *A. albiparvus*, Arrib, and *A. aquasalis*, Curry (*tarsimaculatus*, auct) were found to be common in the city. In 1936 a malarial service was instituted, the work of which included the inspection of dwelling-houses, the collection and identification of mosquito larvae and adults, and the preparation of blood smears. Tables and graphs are given showing data obtained in 1937-41 on the incidence of *Plasmodium falciparum* and *P. vivax* in persons of different age-groups, and on the distribution of Anopheline breeding places. The larvae most commonly found were those of *A. aquasalis*, *A. argyritarsis*, *A. albiparvus*, *Aedes scapularis*, Rond, and *Anopheles triannulatus*, Neiva & Pinto (*bachmanni*, Petrocchi), in that order. Adults of the first three species and of other

density. In uninfected children, the percentage is 2-4, in those with a low density it rises to 3-6 and in those heavily parasitized it may be over 12. The author concludes that persistent sub-clinical infections in African children are accompanied by increased erythropoiesis, the increase being related to the density of the infections.

P. C. C. Garrahan

CICCONARDI A. & ALFANO A. Sul reticolocitotropismo dei plasmodi nella malaria. Nota V.—Il diametro medio delle emazie mature e dei reticolociti durante l'accesso tertanario da *Plasmodium vivax*. [Reticulocytotropism of Plasmodia. V Diameter of Mature Erythrocytes and of Reticulocytes during *P. vivax* Infection.] *Atta Med. Italiana*, 1948, Jan., v 3 No. 1 13-17 English summary

The authors have studied the blood cells during attacks of *P. vivax* infection. As regards uninfected cells it is possible to identify macro-erythrocytes and macro-reticulocytes. Infected cells gave an average diameter which is greater than that of uninfected cells. The average diameter of infected red cells is very near that of infected reticulocytes.

C. M. Wrenyon

ANDREWS W. H. H. & MARGRAITH B. G. The Pathogenesis of the Liver Lesion due to the Administration of Carbon Tetrachloride. *Aust. Trop. Med. & Parasit.* 1948, Apr., v 42, No. 1 85-100 8 figs. on 2 pls. [30 refs.]

The effect on the liver of carbon tetrachloride, chloroform, and phenylhydrazine has been investigated in the course of experiments designed to elucidate the pathogenesis of the centrilobular changes found in malaria. Most of the experiments were made on rats, but other animals were also used. All the drugs produce central necrosis of the liver. The pathological changes are well-known, and are described briefly. In most species the necrosis was accompanied by swelling of the parenchymal cells in the mid-zone causing narrowing of the sinusoids. These vascular changes were investigated in greater detail by injection of Indian ink into the splanchnic system. In animals which had received carbon tetrachloride the penetration of Indian ink into the liver lobules was much reduced.

In the discussion it is pointed out that poisons which cause central necrosis of the liver cannot do so by a direct toxic action on the liver cells, for in that case the cells most affected should be those first reached by the drug at the periphery of the lobule. It is suggested that the necrosis is produced indirectly: swelling of the parenchymal cells obstructs the blood flow to the centre of the lobule and the resultant anoxia leads to necrosis. It is not clear whether this swelling is a direct effect of the poison or whether it also is a result of anoxia, caused by a reflex constriction of the blood vessels. There may be other mechanisms causing central necrosis, since in some cases congestion and not constriction of the sinusoids is found after giving carbon tetrachloride.

[This paper should be read in conjunction with that of GILMAN and HILSON (1948, *Clinical Science*, v 6, 235) who injected Indian ink into the spleen of rats at varying intervals after a dose of carbon tetrachloride. They found the same impairment of penetration of the ink into the centrilobular sinusoids, and drew the same conclusions. These authors pointed out that both carbon tetrachloride and ligation of the blood vessels to the liver produce central necrosis, and in both cases there is a time-lag of 4-8 hours before the necrosis is fully developed. This is further evidence of a common factor in the two processes, which may be anoxia. They also observed that necrosis may occur in other conditions in which the liver cells are swollen, e.g. when they are loaded with fat.]

Studies of this kind are clearly relevant to any discussion of the relation between interstitial tissue and parenchyma.] *J C Waterlow*

SCHNEIDER, T **Haematemesis in Malaria** *South African Med J* 1948, Apr 24, v 22, No 8, 289-91

This report concerns an African male of about 38 who was admitted to hospital in Johannesburg in May 1946 with headache and dizziness which had been present for a week, during which he had had one attack of unconsciousness and one attack of haematemesis. He had no history of gastric symptoms, he had visited a malarial area the month before, but had no personal history of malaria.

On admission the patient had a temperature of 102.4°F and looked ill, but examination revealed little of note, except the examination of the blood. This showed the haemoglobin to be 20 per cent, and the erythrocytes 1,140,000 per cmm. No malaria parasites were found. Despite daily slow transfusions of citrated blood, haematemesis and melaena occurred, the former being severe and persistent and being a daily feature. Hiccough appeared and became almost constant and the patient's condition was deteriorating. Ten days after admission, the erythrocytes were 1,430,000 per cmm and the haemoglobin 24 per cent, and the anaemia was reflected in the blood picture. On this occasion, however, many *P falciparum* parasites were found in the blood. Quinine bisulphate was given (10 grains, t.d.) and haematemesis stopped within 24 hours. Quinine was continued, the temperature fell to normal, and the haematemesis, melaena and hiccough disappeared. After a course of mepacrine, the patient made a good recovery and left hospital seven weeks after admission. An X-ray examination revealed no sign of gastric or duodenal ulceration.

A feature of the case was that the prothrombin index, bleeding time and clotting time were normal. The author compares this with other cases in the literature. The cause of the haematemesis is discussed and the author concludes that the condition was due to a toxic process leading to gastrostaxis initiated by the malarial parasite, since other causes would not be expected to result in so dramatic a response to quinine. Malaria should be considered as a possibility in cases of haematemesis coming from malarial areas.

COATNEY, G R, COOPER, W C & RUHE, D S **Studies in Human Malaria. VI The Organization of a Program for testing Potential Antimalarial Drugs in Prisoner Volunteers** *Amer J Hyg* 1948, Jan, v 47, No 1, 113-19, 1 fig

In studies designed to test the comparative efficacy of drugs, old and new, in the treatment of malaria, an important contribution was made by white volunteer prisoners in the United States Penitentiary, Atlanta, Ga., who willingly underwent the discomforts and uncertainties both of malaria and of the experimental drugs. This paper describes the organization of these studies. One hundred and twenty volunteers were infected with malaria by the bites of infected *A. quadrimaculatus*. The St Elizabeth strain of *P. vivax* was used to infect 105. The remainder were infected with the Chesson strain which

originated in New Guinea. The complete testing of a drug included a long term protective test, a short term protective test, and therapy during acute attacks of malaria. Observations were made on toxicity and quantitative estimations of drug in plasma or whole blood were carried out. Observation of patients continued for 18 months after exposure to infection. *Norman White*

COATNEY G. R., COOPER, W. C., ROME D. S., JOSEPHSON E. S., YOUNG M. D. & BURGESS R. W. Studies in Human Malaria. VII. The Protective and Therapeutic Action of Quinine Sulfate against St. Elizabeth Strain Vivax Malaria. *Amer J Hyg* 1948, Jan. v. 47 No. 1 120-34 8 figs.

In the studies referred to above quinine sulphate was the first drug used. It was considered to be the logical standard of reference. Thirty volunteers were used in the protective tests. Each was exposed to the bites of 10 infected *A. quadrimaculatus*.

Quinine sulphate 0.5 gm. daily for four days before infection, on the day of infection, and for 20 days thereafter suppressed the early primary attack in all cases. Primary attacks occurred after prolonged latent periods of 230 to 332 days. A dose of 0.25 gm. a day for the same period failed to suppress the early primary attack in four of five individuals.

Doses of 2.0 or of 0.5 gm. daily from the fourth day before to the sixth day after infection failed to suppress the early primary attack.

In the treatment of the acute attack doses of 2.0, 1.0 and 0.5 gm. daily for 8 days were used. Parasites disappeared and fever was controlled in all cases, the rate of action being roughly proportional to the dose used. Relapses occurred after intervals that were not influenced by the dose of quinine given in the treatment of the previous attack.

Toxic symptoms were frequent and at times severe: tinnitus, partial deafness, blurring of vision, nausea and vomiting and urticaria, in that order of frequency were noted. *Norman White*

YOUNG M. D. & EYLES, D. E. The Efficacy of Chloroquine, Quinacrine, Quinine and Totaquine in the Treatment of *Plasmodium malariae* Infections (Quartan Malaria). *Amer J Trop. Med* 1948, Jan. v. 28, No. 1 23-8, 3 figs.

Fifty four neurosyphilitic patients both white and negro were infected by the injection of blood containing *P. malariae*. When treatment started, 41 of these patients had experienced 15 or more febrile paroxysms. In some the infections had recently become asymptomatic but parasites persisted in the peripheral blood. The dosage of the drugs used was —

Chloroquine 0.6 gm. followed 6-8 hours later by 0.3 gm. 2nd and 3rd days, 0.3 gm. in single dose each day. In some cases the single daily 0.3 gm. doses were continued to and including the 6th day.

Quinacrine (mepacrine) 0.1 gm. thrice daily for 5 days, or three doses the first day 1.0-4 0.3 and 0.3 gm., followed by 0.1 gm. thrice daily for 6 days.

Quinine 0.67 gm. thrice daily for 4 days then 0.67 gm. daily for several weeks.

Totaquine 0.67 gm. thrice daily for 14 days.

A comparison was made of the rates of elimination of parasites under each of these treatments. Chloroquine gave the best results. Quinacrine was most effective than quinine. Totaquine gave the poorest results. *P. malariae* responded relatively slowly to all the drugs tested. Chloroquine eliminates *P. malariae* parasites much faster than *P. malariae* parasites from the blood even when the densities of *P. malariae* parasites are several times higher. There was

no evidence that increased amounts of acquired immunity accelerate the action of antimalarial drugs in clearing the blood stream from parasites

JAILER J W, ZUBROD, C G, ROSENFELD, M & SHANNON, J A Effect of Acidosis and Anoxia on the Concentration of Quinacrine and Chloroquine in Blood *J. Pharm & Exper Therap* 1948, Mar, v 92, No 3, 345-51 [13 refs]

SHANNON *et al* [this *Bulletin*, 1945, v 42, 343] drew attention to the great variations in plasma levels of quinacrine (atebrin) in individuals on the same dosage schedule. Recently the same authors [this *Bulletin*, 1948, v 45, 575] have indicated the effect on excretion of this and other drugs caused by oral administration of acid and alkali. The concentration of quinacrine in the tissues of animals was shown by MARSHALL & DEARBORN [this *Bulletin*, 1947, v 44, 292] to be more constant than in plasma and there was a greater correlation with intake as well as with suppressive effect on avian malaria. In the present investigation, the acid-base balance of blood and its degree of oxygenation were evaluated as factors likely to influence the partition of quinacrine and chloroquine (a 4-amino-quinoline) between plasma and tissues. The drugs were administered daily to dogs in aqueous solution by stomach tube for periods of from 2 to 18 days and treatment ended 24 hours before experiment. Ten dogs received quinacrine and two chloroquine. During experiment the animal, suitably anaesthetized, was allowed to breathe air for a period followed by 10 per cent CO_2 in oxygen to produce acidosis. Anoxia was achieved, after a period of normal breathing, by means of lowered oxygen tension as a result of re-breathing air from which CO_2 was absorbed. Gas analysis and pH measurements as well as estimation of drug levels were made on arterial blood the last named by the method of BRODIE & UDENFRIEND [this *Bulletin*, 1944, v 41, 453]. CO_2 caused a doubling of the drug concentration in plasma and in red cells but no appreciable change in that of muscle or leucocytes. There was a return to normal during the recovery period when air was breathed. The blood during acidosis was fully oxygenated, but the pH dropped to 6.9 and CO_2 content rose steeply. Anoxia, on the other hand, caused no change in the drug concentration of red cells and plasma of dogs provided that the blood remained unaltered. The distribution of both drugs was high in tissue relative to plasma, and acidosis exerts its effect by altering the partition between the two. A considerable rise of concentration in the latter lowered only slightly that of the former. It appeared probable that the relative concentration of undissociated base is responsible for the distribution of drug between plasma and tissues.

LAWANI, A BAZ I & MORKOS, F On the Antimalarial Activity of Nivaquine C *J Roy Egyptian Med Ass* 1947, Dec, v 30, No 12, 665-9

Nivaquine C is 3-methyl-4 (diethylamino-pentyl) amino 7-chloroquinoline hydrochloride. The powder is very soluble in water and absolute alcohol. Tablets of the drug contain 0.1 gm. Nivaquine C is active against *P. praecox* in canaries and it is stated that in human malaria it is schizonticidal, but has a weaker action on gametocytes. The authors quote DECOURT and SCHNEIDER [see this *Bulletin*, 1948, v 45, 148] in Tunis as having treated adults with 0.3 gm for 5 days without any relapses after a year but "the number of cases was not sufficient to allow of definite conclusions to be drawn".

The present authors investigated the antimalarial activity of Nivaquine C on 98 ambulatory patients at Khanka near Cairo. The patients were put on the following schedule —

| | |
|------------|---|
| First day | 3 tablets in the morning 2 tablets in the evening |
| Second day | 2 tablets in the morning, 2 tablets in the evening |
| Third day | 2 tablets in the morning 1 tablet in the evening |

Fourth and fifth day the same dosage as on the third day

All infections were due to *P. vivax* except one which was a *P. falciparum* infection, in which rings and crescents were present. This patient did not complete the treatment.

In 48 cases pyrexia and parasites disappeared after the first day of treatment. The remainder responded after 2 days. Gametocytes required a few days more.

No toxic symptoms were observed. Only 9 patients relapsed, and a table compares these with the monthly incidence of malaria in the various villages concerned for three to five months. This average was about 1% per cent, compared with an average of 9.3 per cent, of relapses among 93 cases treated and followed up during the same period. It would appear that the incidence of malaria among those treated with Nivaquine was less than that in the general population of the villages in which they resided.

It is concluded that Nivaquine is a potent antimalarial drug, which does not produce toxic effects in the doses suggested. It is mainly schizontocidal and gametocytes take a longer time than asexual forms to disappear after its use.

SINGER, H. O. MILLMAN, N. & BOSWORTH, Mary R. Toxicity and Pharmacology of SN 13592. An Analogue of Phenyl Panthothenone. *Proc. Soc. Exper. Biol. & Med.* 1948, Mar. v. 67 No. 3 388-90. (16)

SN 13592 is characterized by an extremely low acute and chronic oral toxicity in several species. Local irritation effects are absent even upon repeated administration. Continued oral feeding of the drug, induces an anemia which gradually disappears after the drug is withdrawn. Although there were no consistent effects on blood pressure and heart rate a respiratory effect was noted. Smooth muscle was generally stimulated by this compound.

YEST, H. R. DDT to control *Anopheles farauti* on Espiritu Santo, New Hebrides Islands. *J. Econom. Entom.* 1947 Dec. 40 No. 6, 62-8, 1 fig

Among the troops on Espiritu Santo and adjacent islands, there were over 400 primary malaria infections in January 1943 and the same number in February. *An. Phlebotomus* is the only anopheline on these islands and all stages are present in all seasons. An attack on this mosquito by the usual methods of control was started and by December 1943 primary infections were

down to 41 for the month for March 1944 the figure was 19. In April of that year DDT became available. Preliminary investigations showed that 10-minute catches in huts by two men averaged 73 *A. farauti* per hut. The DDT was first tested in cages and in the huts and then in July 1944 every hut and building was sprayed with 5 per cent DDT in kerosene at the rate of 1 gallon per 1,000 square feet of surface, by means of a knapsack sprayer. In some cases, 10 per cent DDT water suspension was applied by flit gun. This treatment was later extended to native huts and plantation buildings. Larval control by weekly spraying of breeding places with 2 quarts or more per acre of 5 per cent DDT in kerosene was done by hand sprayers, knapsack sprayers and by aeroplane. No adult *A. farauti* was found during the rest of the year, and while in May, 1 456 larvae had been found in 38,701 dips, in October only 20 larvae were obtained in 42,525 dips. The average military strength during 1944 was just over 40,000 troops, but there were no primary malaria infections during November and December.

GALVÃO, A. L. & DAMASCENO, R. G. Alguns dados experimentais sobre a ação do DDT e do piretro contra o *Anopheles darlingi*. [Experimental Study of DDT and Pyrethrum as Active Agents against *Anopheles darlingi*. Rev. Serviço Especial de Saúde Pública. Rio de Janeiro 1947, July, v. 1 No. 2, 273-92, 3 figs & 5 graphs. [11 refs.] English summary. H. S. Leeson

"1 The *A. darlingi* mortality in a wood house treated with DDT dissolved in kerosene to give a final surface concentration of 2.09 gm. per square meter (195 mgr. per square foot) was determined. The mortality determined eight hours after contact was as follows: —One month post treatment 97.3 per cent, 2 months 96.4 per cent, 3 months, 92.1 per cent, 4 months, 95.3 per cent, 5 months, 72.9 per cent, 6 months, 67.7 per cent, 7 months, 42.2 per cent. In the same period mortality observed in a control house was respectively, in per cent 4.4, 3.9, 3.3, 10.4, 3.7, 4.5, 6.3.

"2 The authors conclude that in houses of wood residual film DDT may be applied at intervals of 4 months in climates in which there is no interruption in *A. darlingi* breeding or perhaps two times a year where winter interrupts breeding.

3 Captures in houses treated with DDT done with windows open and with windows shut showed no appreciable difference from the point of view of prophylaxis. This causes one to predict that this insecticide will be equally effective in the unprotected dwellings of our people in general.

4 The killing of adult mosquitoes with pyrethrum spray reduced their numbers very much on the nights on which it was applied but apparently this reduction did not reach a point where the transmission of malaria would be prevented.

5 The action of pyrethrum was not lasting with respect to *A. darlingi* since there was no considerable diminution in density on the nights subsequent to the spraying.

GARNHAM, P. C. C. The Developmental Cycle of *Hepatocystes* (*Plasmodium*) *kochi* in the Monkey Host. Trans. Roy. Soc. Trop. Med. & Hyg. 1948, Mar., v. 41 No. 5, 601-16. 12 figs (7 coloured) on 4 pls. [15 refs.]

In a preliminary paper [this Bulletin, 1947, v. 44, 882] the author gave a short account of the exoerythrocytic schizogony of *Plasmodium kochi* in the liver of monkeys. In the present paper he gives a more complete account of the developmental cycle of this parasite, which he designates *Hepatocystes*.

P. kochi adopting the name proposed by LEVADITI and SCHÖN in 1932 for the schizont stage in the liver of the baboon, which they did not connect with *P. kochi*. The blood forms of the parasite are all gametocytes, the youngest stage being a minute spot of chromatin with a tongue of cytoplasm in a red blood corpuscle. With growth a large amoeboid ring is formed. The cytoplasm then becomes irregular in shape, and finally by a filling-in process, the spherical gametocyte is produced. The development of the gametocyte occupies 4 or 5 days. The mature gametocytes stain poorly in blood films. With Romanowsky stain the macrogametocyte takes a steely blue colour while the less dense microgametocyte stains a biscuit colour. The pigment is in the form of very fine granules and at no stage does the red blood corpuscle show Schüffner's dots. The nucleus of the male gametocyte is a large, val-shaped pale pink area occupying a third to a half of the parasite. Scattered in the area are numerous deep red granules or threads of chromatin. The nucleus of the female gametocyte is much smaller and consists of a pale pink area with a dense mass of chromatin at the centre. Sometimes the single chromatin mass may be divided in two to six masses. The mature gametocytes appear to be extracellular and slightly larger than the normal red blood corpuscles. Attempts to infect clean monkeys by blood inoculation failed, though, transfer of gametocytes which appeared at once or later and persisted for periods up to 3 weeks took place. Exflagellation of the male gametocytes was easily observed. The infection in the monkey is very persistent and it is supposed that some of the merozoites from the liver schizonts must be asexual in character and able to give rise to fresh schizonts in the liver. The infected animals were not inconvenienced by their infection and showed no variations of temperature from the normal.

The schizogony in the liver has been described in the earlier paper. When a schizont is mature, merozoites are formed and these are scattered amongst the surrounding liver cells. They presumably find their way into red blood corpuscles to give rise to young gametocytes or into parenchyma cells of the liver to develop into schizonts. A liver cell is figured showing two undeveloped merozoites and two larger forms 4 and 5 μ in diameter. In the section, each of these has peripheral nuclei. A similar but larger form 1 $\frac{1}{2}$ μ in diameter is figured. As the parasite grows, the infected liver cell hypertrophies, the parasite becomes irregular in shape and vacuolated while the nuclei multiply. Eventually the parasite assumes the form of a sponge with external protuberances and internal vacuoles. Finally the internal vacuoles coalesce leaving an external band of cytoplasm with irregular processes extending among the liver cells, and a large central vacuole. The cytoplasm is filled with nuclei which eventually form the nuclei of the merozoites. In fixed tissues cut for sections, the cytoplasm in the mature cyst tends to shrink from the surrounding liver cells, appearing as a band of cytoplasm enclosing the large vacuole. When sections of the contents of a cyst are made, the cytoplasm breaks into fragments of various sizes and with Romanowsky stain they take a blue tint with red nuclei. In the early paper these were described as cytomeres but it appears from sections that no definite cytomeres are formed. The mature cysts are referred to as merocysts. Attempts to produce infection in clean monkey by inoculation with the contents of the mature cysts failed entirely.

The tissue phase of development of *P. kochi* is accompanied by highly characteristic cellular reaction. The parasitized hepatic cell hypertrophies enormously with repeated nuclear division. There is no tissue response till the parasite reaches 15 μ or more. Then large numbers of polynuclear leucocytes accumulate and make their way in between the cytoplasmic processes. This may progress till all trace of parasite is lost but in many cases the parasite continues its development. Then various cells of the lymphoid macrophage

system begin to accumulate between the parasite and liver parenchyma. There also appear large giant cells and phagocytic monocytes containing eosinophile granules. The parasite at this stage ruptures and its merozoites are scattered, while the remains of the parasite are invaded by the phagocytes. The site of the old schizont is represented on the liver by small fibrotic spots. Six mature schizonts gave average measurements of 1.8 by 1.3 mm.

Because of the peculiar character of the reproductive process with the production of the large spherical schizont with its central vacuole, the author believes that the parasite does not belong to the genus *Plasmodium*, nor does he agree with HAWKING and HUNT [this *Bulletin*, 1948, v 45, 494] that it belongs to the genus *Haemoproteus*. He accordingly employs the name suggested by LEVADITI and SCHOEN (*C R Soc Biol*, 1932, v 109, 343) naming the parasite *Hepatocystes kochi*.

The paper is illustrated by two coloured plates and two plates of photomicrographs. C M Wenyon

HAWKING, F, PERRY, W L M & THURSTON, June P. Tissue Forms of a Malaria Parasite *Plasmodium cynomolgi*. *Lancet* 1948, May 22, 783-9, 13 figs (7 on 1 pl) [18 refs]

In an earlier paper HAWKING described pre-erythrocytic schizogony of *Plasmodium cynomolgi* in the liver of monkeys after he had been shown these forms by SHORTT, who had found them in monkeys infected by injection of sporozoites [this *Bulletin*, 1948, v 45, 388]. The authors of the present paper give a fuller account of these experiments. They show that after the injection of sporozoites into monkeys the blood is infective to subinoculated monkeys for about 2 hours, after which it is non-infective for 7 days, 21 hours, when it again becomes infective. Study of the parasites which appear in the blood shows that the release of merozoites from the tissue forms is asynchronous and extends over three days. The number of parasites liberated varies from 1 million to 100 or 1,000 million, according to the infecting dose of sporozoites. The inoculation of emulsions of various organs of infected monkeys, including liver in which subsequent examination revealed pre-erythrocytic schizonts, failed to give rise to infections.

In sections of the liver of a 5-day monkey, the parasites measure on an average 12 by 14 μ . They lie in enlarged liver cells, the nuclei of which are unchanged or slightly increased in size. The chromatin masses in the parasite number about 70. In the liver of a 7-day 15-hour monkey, the average size of the parasite is 46 \times 31 μ . The largest form found measured 68 by 61 μ . In one cross-section there may be 100 to 250 masses of chromatin. Parasites very similar were found also in a 7-day 23-hour monkey. In most cases the parasites are roughly ovoid in shape, but sometimes they are quite irregular in outline and may show clefts in their cytoplasm or a tendency to segmentation into a number of separate masses which bear some resemblance to cytomeres. The host shows little tissue reaction to the presence of the parasite, but occasionally a parasite is invaded by polynuclear leucocytes. In one monkey inoculated intracerebrally with sporozoites, a form resembling a schizont was found in the brain. The paper is illustrated by twelve photomicrographs and a drawing showing variations in shape of a schizont in serial sections.

GRAMICCIA, G & BLACK, R H. The Cultivation of Exoerythrocytic Forms of *Plasmodium gallinaceum*. I. A Preliminary Note. *Ann Trop Med & Parasit* 1948, Apr, v 42, No 1, 88-9, 2 figs on 1 pl.

The method differs from that of HAWKING [this *Bulletin*, 1946, v 43, 410] in that infected organs for tissue culture were obtained from birds which had

received intravenous inoculation of blood containing trophozoites of *P. gallinaceum* instead of from birds which had been infected by sporozoites. Quinine (2.5 mgm) was given daily until parasites appeared in the blood, when the dose was doubled.

Typical exo-erythrocytic forms were found in the macrophage-like cells on the eighth day of the culture. P. C. C. Garman

CLARK, Delphine H. & TRIFLER, M. Studies on Parasite-Host Interplay between *Plasmodium gallinaceum* and the Chicken as Influenced by Hydroxynaphthoquinones. *J. Infect. Dis.* 1948, Mar-Apr, 82, No. 2, 133-62, 5 figs. [40 refs.]

It is recognized that some drugs show different activity against the various stages in the developmental cycle of malarial parasites. A study of the action of 2-hydroxy naphthoquinones on these different phases in *P. gallinaceum* infections of chickens is now reported with the object of elucidating some of the factors in the host and parasite which influence the activity of an antimalarial agent. The effect of the series of 2-hydroxy-naphthoquinones synthesized by FIESER, on carbohydrate metabolism and respiration of erythrocytic forms of *P. knowlesi* and *P. falciparum* was studied *in vitro* by WENDEL (this Bulletin 1947 v. 44, 400).

The chemical constitution of the group differs from that of known antimalarials. In early observations on *P. gallinaceum* infections, it was found that they possessed activity against erythrocytic and exoerythrocytic forms and showed promise as prophylactic agents. The member of the group with which most of the present experiments were conducted was 2-hydroxy-3,5-decyl-1-1-naphthoquinone, which occurs in a number of stereo-isomeric forms each of which may differ in antimalarial activity. In some cases a mixture preponderating in *cis*-forms was used.

Infection was induced in young chickens by graded intravenous inoculations of infected *Aedes aegypti* mosquito suspensions prepared by grinding, etc. of parasitized blood, dosage being based on the size of the host. The course of the blood infection was followed in stained films and that of exoerythrocytic forms in smears of brain or by the method of COCHRAN *et al.* (this Bulletin v. 1945 v. 42, 699) as well as by subinoculation of fresh hosts. As a further test for sterilization of infection in an experimental bird the method of superinfection was used. Drugs were administered in the diet in capsules or intramuscularly in an emulsion of peanut oil and sometimes intravenously and the levels of the naphthoquinone were determined in plasma by spectrophotometric measurements on isoamyl alcoholic extracts of the highly coloured sodium salts.

When the drug was administered prophylactically prior to parasite inoculation of chickens parasites could not be detected in blood or brain smears by the methods outlined, in contrast to the results obtained with control or parasite-treated hosts. In subsequent experiment in which drug was given *after* sporozoite inoculation in the prepatent and also in the patent period it was shown to be very active on the earliest phases of the developing parasite and was less active against the phase present four days after inoculation. By careful timing of drug administration a significant result was obtained that the effect was against the sporozoite itself and complete prophylaxis was attainable. The naphthoquinone was also shown to be active against late exoerythrocytic forms of *P. gallinaceum*. Treatment of patent blood infections disturbed the mechanism of the developmental cycle and growth was retarded.

Comparison of the activities of the naphthoquinone and chloroquine (mepacrine) in blood-induced infections showed that all three reduced the number

of parasites in the peripheral blood, but differences in their activity were obvious when inocula of various sizes were used, the naphthoquinone being generally the more active and there was a maximal inoculum which could be controlled by each drug. The development of immunity was believed to play an important part in the "cures" obtained. The level of drug in the plasma influenced the rate of response to treatment. Chronically infected birds showed greater immunity than those treated early in the infection. The immune state of the latter appears to offer further opportunities for studying the factors affecting latency, relapse and cure in this infection. Therapeutic treatment involves an interplay between parasite, host and the agent used. The results described here are in general agreement with those of GINGRICH *et al* [this *Bulletin*, 1947, v 44, 803] who reported cures in canaries infected with *P. cathemerium* on treatment with the same naphthoquinone. [This careful and extensive analysis of the factors which come into play during treatment of the different phases of a malarial infection merit consultation of the original article.]

RIGDON R H & McCAIN B E Effect of 3,3'-Methylenebis (4 Hydroxycoumarin) "Dicoumarol" on *P. lophurae* Infection in Ducks (4 Hydroxycoumarin) *Malaria Soc* 1948, Mar, v 7, No 1, 38-43, 2 figs

J National

When dicoumarin (3,3'-methylene-bis-4-hydroxycoumarin) was given in repeated doses by mouth to young white Peking ducks infected with *P. lophurae* it was found that the degree of parasitaemia was reduced in comparison with controls. The development of a peak of parasitaemia was also delayed and deaths occurred earlier in these treated birds. In a typical experiment with a group of 40 ducks about 3 weeks old 10 were infected with *P. lophurae* and 15 others uninfected were given similar doses of the drug ranging from 25 to 100 mgm on 5 to 7 occasions. Parasite counts were made in the usual way in stained films. In the control animals anaemia, acidosis and haemorrhages in subcutaneous tissues were noted. Death appeared to be due to acidosis rather than anaemia and sometimes occurred rapidly in birds on low vitamin A intakes. The plasma was not coloured by haemoglobin but its CO₂ combining power was reduced. The drug is obviously of no value in treatment and the mechanism by which it produced the above effects is not known.

J D Fulton

WALKER, H A STAUBER, L A & RICHARDSON, A P Curative Action of Pamaquine Naphthoate, Quinaquine Hydrochloride, and Quinine Bisulphate in *Plasmodium cathemerium* Infections of the Duck

J Infect Dis 1948, Mar-Apr, v 82, No 2, 187-96, 3 figs

Screening tests for antimalarials were widely developed during the late war with the use of a number of different host species and parasites. While many drugs showed suppressive activity, cures were less readily obtained. Two reports of tests for curative action have been described by KELSEY *et al* and by DEARBORN & MARSHALL [Proc Fed Amer Soc Exp Biol, 1946, 185, this *Bulletin* 1946 v 43 404] who used respectively *P. lophurae* infections of the chick and duck. The present authors now describe a curative test with *P. cathemerium* infections in the duck whereby certain drugs active in human malaria infections have been evaluated.

Peking ducks 10 to 12 days old of approximately 150 gm. were inoculated intravenously with 5×10^4 parasites per kgm. of body weight. At the peak of infection on the 4th day 30 to 50 per cent. of the red cells were parasitized and by the 8th day parasites could not be found in thin films of peripheral blood of untreated fowls although it remained infective for fresh hosts over a period of some months. Different dosage schedules for each drug were used on 10 to 15 ducks one day before and for six days following inoculation. The drug diet method or stomach tube was used for administration. A regular 3 hour dark and 3-hour light cycle was automatically maintained. Blood smears from each host were examined one day after the end of treatment and weekly thereafter till the 30th day from inoculation or on death of a bird. At the end of the observation period fresh hosts were inoculated from the experimental birds and their blood was examined on alternate days for 15 days, a period regarded as suitable from other experimental observations. The donor birds were in turn inoculated with 5×10^4 parasites per kgm. of body weight and blood smears were made 3 days later and the nature of the resultant infection, if any noted. Before a duck was regarded as cured, smears had to remain negative over the observation period and the bird subinoculated from it had to remain free from infection. Finally the challenging dose: the donor bird had to give rise to a normal acute infection. Subinoculation and reinfection were regarded as a more accurate index of cure than absence of parasites in the treated birds. A few discrepancies were however encountered in these two criteria in so far as both might be positive or both negative. In all, 147 ducks were treated with different drugs and 289 satisfied all three criteria: 1 cure, Pamaquin (plasmoquine) because of its properties was adopted as the standard in these experiments and effected a number of cures so also did quinacrine (atebrin) but not quinine. Results with 8-aminoquinolines other than pamaquin suggested a correlation between the present results and those recently obtained in man.

J. D. Fulton

WALKER, H. A. & RICHARDSON, V. P. Potentiation of the Curative Action of 8-Aminoquinolines and Naphthoquinones in Avian Malaria. *J. National Malaria Soc.* 1948, Mar. 7 No. 1: 4-11

Synergistic action between therapeutic agents of different chemical constitution against parasitic infections has frequently been noted. It is due possibly to the effect of these agents on different vital processes in the parasites. Such an action is now recorded in *P. cathemerium* infections of ducks between 8-amino-quinolines represented by plasmoquine (pamaquin) and pentaquine (SN 13,276) and three naphthoquinones (SN 5949, SN 12,333 and SN 13,336). Birds 10 to 12 days old weighing about 150 gm. were divided into groups of 10 to 20 and each was inoculated intravenously with 5×10^4 parasitized cells per kilo of body weight from a donor bird. Drug-diet therapy at different dosage levels was started 16 to 18 hours before inoculation and continued for 6 days thereafter. Examination of the host blood for parasites was made at intervals for several weeks after infection. Following blood examination 23 days after inoculation, each host was re-inoculated with the same number of parasites as in the first instance and blood smears were examined three days later. Absence of parasites during regular examinations after treatment was used as one criterion, and the other which the authors consider more significant was the attainment of a sufficiently high level of parasitaemia after reinoculation. It was shown that pamaquin, pentaquine and SN 12,333 given alone were curative but the dosage required for 100 per cent. elimination of the infection was liable to produce fatal toxic effects. Pamaquin was more active than pentaquine, and showed about 20 times the activity of SN 12,333. Synergistic

effects were observed in various combinations of the two different types of drug in curative therapy, but were much less marked in suppressive therapy, suggesting that the mechanism in the two cases was different. From other experiments it appeared that SN 12,320 alone was more effective in the cure of well-established infections. The value of similar combinations to the above in the treatment of human malaria, as well as the mechanism by which the effect is produced, has yet to be determined.

TRYPANOSOMIASIS

ERRATUM

In the *Summary of Recent Abstracts, Trypanosomiasis*, this *Bulletin*, 1948, v 45, at the foot of page 383, the following sentence "The author [VAN HOOFF] thinks that melarsen oxide is useful for the treatment of patients with resistant strains (a conclusion not shared by LOURIE)" does not correctly represent the views of Lourie, who shows, on p 413 of the same issue, that he has confirmed van Hooft's findings. The phrase in brackets, therefore, should be deleted.

Charles Wilcocks

NASH, T A M A Note on the Effect of High Temperature on the Pupal Stage of *Glossina* in relation to the Transmission-Rate of Trypanosomes. *Ann Trop Med & Parasit* 1948, Apr. v 42, No 1, 30-32

In BURTT's experiments [this *Bulletin*, 1946, v 43, 827, 1947, v 44, 803] tsetse flies (*Glossina morsitans*) which hatched from pupae incubated at about 86°F showed a greater transmission rate for *Trypanosoma rhodesiense* than those hatched from pupae kept at the lower average temperature of the laboratory. In Northern Nigeria, NASH [this *Bulletin*, 1942, v 39, 532] found many pupae of *G. submorsitans* in soil at temperatures ranging from 69° to 82°F but very few at higher temperatures, and as the shade temperature reached 106°F (probably as high as anywhere in Africa) it is probable that BURTT's pupae were incubated at a higher temperature than they would experience in nature. his experiments should be repeated to compare the effect of temperatures of 68° and 82°F.

The author's work in Nigeria [see also this *Bulletin*, 1937, v 34, 533, 1940, v 37, 15] led him to conclude tentatively that most sleeping sickness conveyed by the riverine tsetse flies *G. palpalis* and *G. tachinoides* is contracted in the late dry season when the soil temperature is high and when the flies have become restricted to permanent water pools such as the village water holes. here contact between the flies and the people is close and the flies are compelled to feed largely on human beings. Confirmatory evidence for this view was not obtained from the dispensaries as the disease is mild in character and the people present themselves late for treatment. If it should be confirmed it may be possible to reduce the length (and cost) of protective clearings of river crossings to that required for the dry season only.

KLEINE, F K Unterschiede in der Bekämpfung der afrikanischen und der russischen Trypanosomiasis [Differences in the Control of African and Russian Trypanosomiasis] *Ztschr f d Deut Gesundheitswesen* 1946 v 1, No 6, 143-4

Domestic animals in southeastern Russia, where camels are much used in agriculture, are infected with surra (*Trypanosoma evansi*), as the trypanosome

is directly and mechanically carried from one animal to another by tabanid and other biting flies which do not themselves become infected, the control of surra would seem to be less difficult than that of those African trypanosomes transmitted by tsetse flies which become infected and form an additional reservoir of the trypanosomes. The author refers briefly to the various well-known methods of controlling trypanosomiasis in man and animals.

As *T. cruzi* and *T. brucei* resemble each other so closely in appearance it is thought that they are nearly related, but the former apparently cannot develop in tsetse flies. HUNTER and KRAUSE [this Bulletin 1934 v 31 597 1935 v 32, 362] failed to infect *Glossina morsitans* with a strain of *T. cruzi* isolated less than a year previously. [As was noted by the reviewer of their papers the direct transmission of *T. cruzi* by *G. morsitans* as late as the 3rd and 5th days after they had fed on an infected animal is remarkable. Further experiments on direct transmission of pathogenic trypanosomes are desirable.]

J. F. CORRIE

KENEFORD J. R. LOURIE, E. M. MORLEY J. S. SIMPSON J. C. E. WILLIAMSON J. & WRIGHT P. H. Cinnoline Derivatives as Chemotherapeutic Agents for *Trypanosoma congolense* Infections. [Correspondence] Nature 1948 Apr 17 603-4

The authors have synthesized quaternary salts of various mono- and diamino-cinnolines -quinazolines and -quinolines in which substituent amino groups can be more readily introduced than is the case with the more complex phenanthridinium compounds of the type described by BROWNING *et al.* [this Bulletin, 1938 v 35 344]. The latter compounds, especially dimidium bromide (1533) and phenidium chloride (597) are the most active substances so far described for the treatment of *T. congolense* infections of cattle in Africa. Two substances 4, 6-diamino-1-methylcinnolinium iodide and a derivative methylated in position 3 were found to be inactive against *T. congolense* in culture when pure whereas the impure products of reduction had comparable activity to that of "597" but were much less active than 1533. The impurities in the two compounds were believed to arise from side reactions during reduction of the 6-nitro precursors and are possibly comparable with symmetrical structures. Attention is drawn to the trypanocidal activity of certain other non aromatic compounds with symmetrical molecules. Analogous activity of symmetrical sex hormones suggests that symmetrical compounds with the type of structure suggested for the above active products may provide useful trypanocides.

WILSON S. G. Further Observations on the Curative Value of Dimidium Bromide (Phenanthridinium 1533) in *Trypanosoma congolense* Infections of Uganda. J. Comp. Path. & Ther. p. 1948 Apr. Vol. No. 6

HARVEY S. C. Sulfhydryl and Disulfide Content of Normal and Antimony-Resistant Trypanosomes. Proc. Soc. Exper. Biol. & Med. 1948 Mar. v 67 No 3 269-72. 1 ref.]

VOEGTLI and co-workers this Bulletin 1941 1 414 1945 v 42 116 showed that the -SH group was present in certain trypanosomes and suggested that trivalent arsenical was capable of combining with it. It is suggested that a similar grouping may also combine in the same way. The active principle of the tripeptidyl glutathione which in the reduced form contains a free -SH group, was believed to play a part in the pleomorphicity of antimony-resistant trypanosomes. A quantitative estimation of sulfhydryl

groups (capable of yielding the former on reduction) in normal and arsenic-resistant strains of *T. equiperdum* and *T. hippicum* was therefore made, in order to test the truth of the above view. For this purpose, the trypanosomes were obtained free from red cells by centrifuging the blood of infected rats. The washed preparation was mixed with 15 per cent trichloroacetic acid and the solid obtained on centrifuging was resuspended and treated in the same way. The product was then suspended in dry acetone and shaken with the addition of a drop of concentrated HCl. After centrifuging the same process was repeated. On removal of the liquid *in vacuo*, the residue was ground to a fine powder and dried at 105°C for 30 minutes. The method of MIRSKY and ANSON (*J Gen Physiol*, 1935, v 18, 307) was used for the estimation of —SH groups before and after reduction and the content of —S—S— groups present was obtained by difference. The values for the —SH groups present in normal and arsenic-resistant forms of both species of trypanosome showed differences which were not regarded as significant. The normal strain of *T. equiperdum* however contained an excess of disulphide groups compared with the resistant form, while in the case of *T. hippicum* the reverse was the case. There was no indication of a definite relationship between actual and potential —SH content of the trypanosomes and arsenic-resistance, and on this basis also no explanation was forthcoming why certain arsenicals with an acidic side chain are effective against arsenic resistant forms.

CHEN, G & GEILING, C M K. The Effect of Cysteine on the Antitrypanosome Activity of Antimonials. *J Infect Dis* 1948, Mar–Apr, v 82, No 2, 131–2.

The authors [this *Bulletin*, 1945, v 42, 869] showed that the trypanocidal activity and toxicity of trivalent, but not of pentavalent antimonials, for mice, was reduced by cysteine. The inhibitive effect of both types of compound on glucose metabolism of the trypanosomes was also antagonized by this substance *in vitro*. The effect on the trypanocidal activity of tartar emetic, sodium-antimony-thioglycollate, stibamine and neostibosan as judged by sugar metabolism *in vitro* has now been investigated by the methods previously described [this *Bulletin*, 1946 v 43, 315]. Cysteine hydrochloride brought to pH 7.5 by trisodium phosphate was added to the trypanosome suspension at different intervals of time after the administration of the drug during the observation period of 1 hour. It was found that cysteine was able to antagonize the inhibitive effect of both the trivalent and pentavalent compounds on the glucose metabolism of *Trypanosoma equiperdum*. Experimental data in the case of stibamine indicated that there was a lag in the effect produced by this drug on trypanosome metabolism, in agreement with the delayed toxic effects produced by the same substance in mice compared with trivalent compounds. The possibility that the pentavalent antimonials exert their trypanocidal activity after reduction has frequently been suggested, but proof is still lacking.

CHEN, G. The Effect of Methyl-Bis (β-Chloroethyl) Amine on *Trypanosoma equiperdum*. *J Infect Dis* 1948, Mar–Apr, v 82, No 2, 133–7, 1 fig.

The effect of methyl-bis (β-chloroethyl)-amine (nitrogen mustard) on the glucose metabolism, morphology, motility, survival and reproductive powers *in vitro* of *T. equiperdum* has been investigated.

The effect of cysteine hydrochloride brought to pH 7.5 by trisodium phosphate was tested as an antagonist of the action of this drug. The methods for studying glucose metabolism have been described [this *Bulletin*, 1946, v 43, 315]. After

the drug in suitable medium had been mixed with heparinized blood from an infected rat, the effect on reproduction was investigated by studying the number of dividing forms present in stained smears. Those with two parabasal bodies were put in this category. The infectivity for mice of trypanosomes kept in a concentration of the drug, which over a period of 1 hour did not produce any morphological changes, was also determined after centrifugation and replacement of the medium. The effect of the nitrogen mustard on the course of the infection in rats was also studied, but the substance proved very toxic for these animals. An inhibitive effect on glucose metabolism was shown by a 10^{-3} molar concentration of the drug which is therefore less effective than tartar emetic or stibamine. With 5 times the above concentration, motility of the trypanosomes in suspension was impaired after 1 hour without significant reduction in numbers and their morphology was at that time unaltered, but some change was evident after two hours. Dividing forms were reduced in number after exposure to a 5×10^{-4} molar concentration of the drug for 2 hours. The specific effect on the reproduction was shown by inoculating mice which had been subjected to different molar concentrations of the drug for 1 hour. From the increased survival time of the infected animals the minimal effective molar concentration of drug appeared to lie between 10^{-3} and 10^{-4} while a maximal effect was produced at 10^{-3} . The mechanism of the effect on multiplication was studied by investigating the relationship between the dose of treated trypanosomes and the survival time. It appears that certain phases of mitosis are inhibited. Cysteme was able to antagonize the effect of the nitrogen mustard.

LEISHMANIASIS

GHOSH, H. & GHOSH, N. V. Complement-Fixation Reaction in Sera of Rabbits actively immunized with Living Culture of *Leishmania donovani*. *Ann. Biochem. & Exper. Med.* Calcutta, 1947 v 7 No. 1/4 12

— & — Agglutination Reaction in Sera of Rabbits Immunized with different Strains of *Leishmania donovani*. *Ibid.* 3-6. (17 refs.)

Three rabbits were immunized by intra-venous injection of live cultures of *Leishmania donovani* six times at intervals of four days. The dose of organisms was 100 million increased to 1 000 million.

In the first paper the titre of the complement fixing antibodies is given as 1 in 8,000 1 in 6,000 and 1 in 14,000. The complement fixation reaction was carried out with an emulsion of flagellates in 0.25 per cent phenol in distilled water the emulsion containing 60 million organisms per cc.

In the second paper the agglutination reaction of the sera is described. Various antigens were prepared from culture flagellates. The titres of the immunized sera were 1 in 24,000 1 in 16,000 and 1 in 32,000. There appears to be no H or O antigen in *Leishmania donovani*. C. M. Wray.

LUARIZ, J. M. Pathology of Kala-Azar. Report of a Case. *Am. J. Trop. Med.* 1946, Mar., v 23 No 2, 275-83 8 figs. (11 refs.)

The author gives a short review of the pathology of kala azar and reports the autopsy findings in one case.

The subject was an East Indian seaman from Calcutta. Diagnosis was made by sternal puncture. A spleen puncture was also performed and the man died six hours later. The clinical aspects of this case have been reported previously [this *Bulletin*, 1947, v 44, 986].

The abdominal cavity contained about 4,000 ml of bloody fluid. There was a small round puncture hole on the convex surface of the spleen about 2.0 mm in diameter. No blood clot or fibrinous deposit was seen on the capsule. The spleen weighed 1,030 grammes. The capsule was tense and the friable red pulp bulged above the cut surface. The liver was flabby and soft and the cut surface had a nutmeg appearance. There was a large area of broncho-pneumonia in the upper lobe of the right lung and scattered foci in the lower lobe. Small superficial ulcers surrounded by minute haemorrhages were noted in the rectum.

Microscopic examination of the spleen showed atrophic and scanty Malpighian follicles and highly cellular red pulp with enlarged and rounded reticular cells, some of which were parasitized. There were fatty changes in the liver parenchyma cells and hyperplasia of the Kupffer and interstitial cells, parasites were seen in the latter. In the bone marrow there was increased cellularity, the bulk of which was "clasmocytic tissue", many leishmaniae were seen. Leishmaniae were not found in the lymph glands or in other organs and tissues.

In the brain, there was a 'ring haemorrhage' in the basal ganglia and a small focus of gliosis in the pons. It was not decided whether these changes were due to kala azar or to some other conditions.

There are 7 good photomicrographs, and one photograph showing the cut surfaces of the liver and spleen.

CARTWRIGHT, G. E., CHUNG, H. L. & CHANG, A. Studies on the Pancytopenia of Kala-Azar. *Blood* 1948, Mar, v 3, No 3, 249-75, 13 figs [39 refs].

The authors commence with a summary of the previous work on the blood picture in kala azar. The summary is a comprehensive one as far as work in China is concerned.

The present study is based on findings in 143 cases of kala azar diagnosed by the demonstration of *Leishmania donovani*, of these, 27 were studied in great detail and the analysis of the findings in these cases forms the main body of this paper.

Anaemia was constant. The average haemoglobin for 124 uncomplicated cases was 8.3 grammes per cent. In one-third of the patients it was below 7 grammes per cent. The anaemia was significant (10.6 grammes), it occurred immediately after the onset of symptoms and was subsequently progressive. There was a positive correlation between splenic enlargement and anaemia.

The anaemia was normocytic orthochromic. Leucopenia was an almost constant feature of uncomplicated kala azar. The average white cell count of 124 patients was 2,835 per cmm. Only 16 patients had a white count above 5,000 per cmm. The leucopenia was apparent at the time of onset of the symptoms and it increased slightly in intensity with the progress of the disease. There was a correlation between a low white cell count and splenic enlargement.

The platelets were reduced in the majority of cases, the average in uncomplicated cases was 103,000 per cmm (330,000 being normal by this method). The thrombocytopenia developed later, it was not usually present until two months after the onset of symptoms, but was progressive subsequently. In the presence of severe complications, e.g., noma, the thrombocytopenia was more marked.

The bone marrow was always hyperplastic, reticulo-endothelial cells constituted 5 to 50 per cent of the total cells, but all the blood-forming cells were present, and the authors consider that the reticulo-endothelial proliferation is

mainly at the expense of the fat. The proportion of reticulo-endothelial cells tends to increase with the duration of the disease. One to 60 per cent. of the reticulo-endothelial cells were parasitized.

A table shows the bone-marrow differential counts in 27 cases. Polymorphonuclear leucocytes were reduced from the normal of 20 per cent. to a mean of 3.4 per cent. in the 18 uncomplicated cases. This change develops within the first month of the disease. The eosinophils were also markedly reduced; they were often absent in a count of 500 to 1 000 cells. The erythroid cells were increased from a normal of 22 per cent. to 36 per cent. of all cells except reticulo-endothelial cells. The leucocyte-erythroid ratio is shifted from 3.5:1 to an average of 1.8:1.

The number of megakaryocytes was sometimes greater than normal, sometimes less; the average was slightly less than normal, i.e. 122 per million nucleated cells, but platelet production was markedly reduced. Few clumps of platelets were to be seen in the marrow. In the treated cases, there was active platelet production and there were usually more masses of platelets than are seen in normal marrow, although in the peripheral blood the platelets were still short of normal.

The lymphocytes and monocytes were present in approximately normal numbers, but the plasma cells were somewhat increased.

During effective anti-leishmanial therapy parasitized reticulo-endothelial cells disappeared and the percentage of reticulo-endothelial cells gradually diminished as the polymorphonuclear neutrophils increased. There was a significant increase in the eosinophilic cells. Lymphocytes became more numerous and the plasma cells diminished in number. Nucleated red cells became less numerous and the leucocyte-erythroid ratio returned to normal. At the same time the proportion of orthochromatic normoblasts to polychromatic normoblasts increased. The three cellular elements were restored to normal in the peripheral blood in the same order as their reduction from normal.

Evidence is presented which contradicts the view that the pancytopenia is due to a crowding out of the bone-marrow by reticulo-endothelial cells.

Certain similarities between the haematological changes in this disease and those accompanying the hypersplenic syndromes are noted. L. E. V. *per*

SANCHEZ BAYARRI, V. SELVA, J. & MARCO VENTR, R. Formulas hematológicas anormales en el kala-azar [Unusual Blood Findings in Kala Azar] *Med. Colonial, Madrid*, 1948 May 1 v 11 No. 5 383-8.

An account of two cases and a discussion on leucocytosis in kala azar

HO E. Y. SOONG, T. H. & LI Y. Comparative Merits of Sternum, Spleen and Liver Punctures in the Study of Human Visceral Leishmaniasis. *Tr. R. Soc. Trop. Med. & Hyg.* 1948 Mar v 41 No. 5 629-34

In a series of 450 cases of kala azar an attempt was made to appraise the value of the diagnostic methods, spleen, sternum and liver puncture, before treatment. Punctures were performed in other cases during and after treatment with urea stibamide.

The techniques are described shortly. Smears, stained by Wright's stain, were examined.

In a series of 450 cases finally diagnosed as kala azar in which spleen and liver punctures were performed before treatment both punctures were positive in 375 (83.4 per cent.); spleen puncture only was positive in 64 (14 per cent.) and sternum puncture only was positive in 11 (2.4 per cent.). Among the

375 cases in which both punctures showed leishmania, larger numbers were shown in the spleen puncture material in 184 (49.1 per cent) and in the sternum puncture material in 34 (9.1 per cent)

In 121 cases of the same group liver puncture was also done. Of these, in 118 (97.6 per cent) spleen puncture was positive, in 108 (89.2 per cent) sternal puncture was positive, and in 93 (76.9 per cent) liver puncture was positive. In no instance was liver puncture alone positive.

In a series of 203 cases in which the punctures were performed during treatment, leishmania disappeared from both spleen and bone marrow at the same time in 138 (68.0 per cent) instances, in 41 (20.2 per cent) instances the spleen puncture was negative while the sternum puncture was positive and in 24 (11.8 per cent) instances the reverse was the case.

In another 86 cases under treatment, parasites disappeared from the spleen, liver and sternum at the same time in 45 instances, while in the remaining cases they disappeared from the liver first.

After treatment, the "sternum and spleen punctures were found to check up each other very closely."

The authors recommend that both spleen and sternum puncture should be performed to ensure accurate diagnosis. They consider that "once the technique is mastered, spleen puncture is the simplest of the three, but it is not so certain as sternum puncture, especially since the latter can be repeatedly tried without risk at one session." [This statement is not understood.]

There were no ill-effects from the punctures performed in any of their cases.

TRINCÃO, C. A New Reaction for the Diagnosis of Kala-Azar. *a Preliminary Report Amer J Trop Med* 1948, Mar, v 28, No 2, 287-8. L E Napier

While estimating iron in serum, the author noted that when 1 part of hydrochloric acid (0.3N) was added to 2 parts of serum of a kala azar patient, after a short interval the mixture became coagulated in a manner that reminded him "of the phenomenon demonstrated by the well-known formic aldehyde reaction of Napier."

On addition of the hydrochloric acid there is "an immediate slight cloudiness and when the reaction is complete, the jellified serum may take on a darker tinge its initial cloudiness is increased, and, though continuing translucent, it assumes a slightly milky appearance."

The author tried this reaction in four other cases of kala azar, one in an advanced stage of treatment, the rest clinically cured. The first case gave jellification of the serum at the end of 24 hours and all produced a soft jelly. The author has made hundreds of serum-iron determinations and in no other cases has the reaction occurred, except that in a case of multiple myeloma (aldehyde test=++) the serum jellified after 24 hours.

SNOW, J S SATULSKY E M & KEAN B H. American Cutaneous Leishmaniasis. *Report of Twelve Cases from the Canal Zone Arch Dermat & Syph* 1948, Jan, v 57 No 1, 90-101 2 figs [Refs in footnotes] L E Napier

Cutaneous leishmaniasis is uncommon in the Panama Canal zone, only 18 cases have been observed at the Gorgas Hospital since 1904. Of these, 6 were prior to 1937, the remaining 12 cases are included in this report. Very few cases have been reported in the Republic of Panama outside the Canal zone, two references to reports on 8 such cases are given. In 9 of the 12 cases the lesions appeared first in the dry season, January to March. All the patients were males. Six were soldiers from the United States.

and three from Porto Rico. Three were labourers, 2 being Panamanians and one a Colombian.

"All patients had been in the Isthmus of Panama for several months before the appearance of the lesions, so that there is little doubt that they were autochthonous." The estimated incubation period was less than 2 weeks in 4 cases and less than a month in two others.

In nine cases there were single and in three multiple lesions.

The lesions were all on exposed parts of the body. All started as irritating "insect bites" which the patient scratched. All cases presented open ulcers, 0.5 to 9.0 cm. in diameter. The ulcers had raised sometimes undermined borders with bases of granulation tissue. There was usually a copious thick serous discharge but occasionally a purulent discharge. "A striking feature was the occurrence of multiple small subcutaneous nodules along the regional lymphatics in 5 of the 8 patients with lesions of the upper extremity. Most of these showed no inflammatory reaction. Regional lymphangitis and adenitis were also usual.

The histopathology is described in detail. It was noted that the cellular reaction in the subcutaneous nodules resembled closely that seen in the biopsy of the ulcers. Leishmania were found in the latter in each case usually in macrophages but occasionally in epithelial cells, but were not found in the nodules. However some treatment had been given in all the cases examined.

Treatment was by potassium antimony tartrate, Stibophen (Fouadin) or stibamine glucoside (Neostam) intravenously. Immediate (coughing, vomiting and chill) and late (joint pains) reactions occurred with all the drugs, but were most marked with potassium antimony tartrate. Improvement occurred within a week and the average healing time was 5-7 weeks. If the severity of the case was taken into consideration, there was little difference between the results obtained with the three drugs.

L. E. A. JEFF

PEREIRA, S. B. & ROSENBERG, A. Nota sobre o tratamento intensivo da leishmaniose tegumentar americana pelo tartarato de sódio antimonita. [Intensive Tartar Emetic Treatment of American Cutaneous Leishmaniasis.] *Hospital*. Rio de Janeiro. 1947 Dec. v. 22, No. 6 845-52 10 figs.

The authors, following the experience of VIVES and BLAIR (this *Bullet* 1948, v. 43, 344) in the treatment of schistosomiasis by intensive administration of tartar emetic have tested the method in six cases of S. American cutaneous or mucocutaneous leishmaniasis. The solution used was put up in ampoules each containing 0.15 gm. of the salt in 10 cc. of normal saline with 5 per cent. glucose. Three ampoules were administered each day for two days, a total of 0.78 gm. being given in the six injections. In most cases the full course was repeated a second or a third time after three or four weeks. In some cases a modified course was given. The improvement noted in some of the cases would seem to justify further tests of this intensive treatment.

C. M. Wrayne

FEVERS OF THE TYPHUS GROUP

MACCARTHY Ethna. Public Health Problems created by Loose Infection. *Irish J. Med. Sci.* 1948 Feb 6th ser. v. 241 65-78, 2 figs. & 4 maps. [14 refs.]

Among more than 3,500 persons coming from all the counties of Eire for the examination prescribed in the Health Embarkation Scheme for emigrants, high rates of loose infection were found.

Among men, the percentage of infestation with body lice or their nits ranged from 30 to 65 per cent in the different counties, for women the rates were considerably lower, but they refer only to the discovery of live lice and the real rate of infestation was believed to be as high as among the men. Head lice were found in 40 to 100 per cent of the women from different counties.

Out of 401 persons tested by the Weil-Felix reaction, 154 reacted at 1-25 or over against *Proteus OXK*, against *P OX19* and *P OX2* the corresponding reactions were 33 and 37 respectively. The percentages of reactions among persons from "endemic" and "non-endemic" areas were much the same, except for the *P OXK* reaction which was nearly three times more frequent in persons coming from the non-endemic areas.

A titre of 1-125 was reached in only 12 cases, in eight of which the reaction was with *P OXK*, two reactions of this titre occurred with each of the other two strains, including one at 1-250 against *P OX2*.

Two interesting family outbreaks of typhus are mentioned. One of these occurred in Drogheda in 1939 [this *Bulletin*, 1942, v 39, 138], and it was found that every person attacked had engaged in unpacking trunks which contained clothing belonging to "old ladies who had been the sole survivors in their street of an epidemic in 1898". The other outbreak, in Galway in 1926, affected persons who in a search for firewood had broken into an old shack which had remained closed for 15 years since the death, in one day, from typhus fever, of a family of five. The shack contained only one bed. In neither outbreak was there any further spread of the disease and it appeared likely that the infection was caused by dust in which virulent rickettsiae had survived for periods of 41 and 15 years.

John W D Megaw

GIROUD, P & JADIN, J. Diagnostic différentiel des typhus par l'agglutination des rickettsies [The Differential Diagnosis of the Typhus Fevers by Rickettsia-Agglutination. *Bull Soc Path Exot* 1948, v 41, Nos 1/2, 20-25]

The authors state in general terms their reasons for regarding the rickettsia-agglutination test as preferable in ordinary circumstances to the complicated complement-fixation test, as well as to the Weil-Felix and precipitin tests. They claim that the rickettsia-agglutination test of P and M-L GIROUD easily differentiates between epidemic and murine typhus during the 3rd and 4th days of attacks and also after the height of the attacks. The difference between the epidemic and murine titres is less pronounced in the intermediate stage and also when the sera have been inactivated by heating or have been stored for long periods.

John W D Megaw

HIRSZFELD, L. Notes on New Methods in the Investigation of Typhus Fever. *Texas Reports on Biol & Med* 1948, v 6, No 1, 21-2

This work was begun during the German occupation of Warsaw and was temporarily discontinued in 1942, owing to the war.

The author isolated 30 strains of *Proteus X* from blood, urine and postmortem material of typhus patients with the use of Mueller-Kauffmann medium containing ox-bile. The best results were obtained from the inoculation of each tube of medium with 1 to 2 cc of blood from the patient during the second week of the disease. A series of a dozen inoculations from each case is recommended. After 24 to 48 hours' incubation, transfer is made to agar. The strains isolated were agglutinated by the patients' sera in dilutions four times higher than was the case with a standard *Proteus X19* strain.

It was found that the sensitization of red cells influenced their absorption capacity on filter paper. This was applied, apparently with success, in the

cultivation of *Proteus X*. Serum from a typhus patient was added to his urine, which was filtered. Strips of the filter paper were then submerged in the Mueller Kaufmann medium and in a large proportion of our cases *Proteus X* was cultivated."

During this investigation it was found that if patient's serum in decreasing amounts of 0.5, 0.4, 0.3, 0.2, 0.1 and 0.05 cc. was added to five tubes each containing 2.5 cc. of patient's urine, a precipitate was formed "in certain dilutions after 15 minutes" but although this "uroprecipitation" test first seemed to be specific for typhus, it later gave positive results in typhoid and scarlet fevers and also certain anomalous results were found. The author suggests that if uroprecipitation indicates a specific substance there might be also another factor of overlapping antigenicity or an appearance in the urine of substance as a result of colloidoclasia. (This paper is extremely brief and further confirmatory details of the results described would be required before a critical opinion could be offered on them.)

BIRCEANU S. & CUCURBANU Iulia. Studiu asupra turburarilor nervoase din tifosul exantematic. Forme clinice speciale [Nervous Manifestations in Exanthematic Typhus. Special Clinical Types.] *Rev. Stiintelor Med.* Bucharest, 1947 Nov. Dec., v. 38 Nos. 11/12, 494-502. French summary.

During the course of an epidemic of typhus in Bucharest in 1943, 230 cases were examined by the authors. In 141 of these, nervous symptoms dominated the clinical picture. Confusion was observed in 55 cases, dysarthria in 15, deafness in 17, blindness in 1, strabismus in 1 and nystagmus in 2 cases. 3 cases were bulbar and 16 meningeal in type. In all 230 cases there was some degree of cellular reaction in the cerebrospinal fluid. This was often slight in the presence of severe meningeal symptoms, and these cases formed a well-defined type of serous meningitis. A type was also seen where symptoms were predominantly those of compression due to cerebral oedema or increased pressure of the cerebrospinal fluid. These cases included 3 of hemiplegia and one with cerebellar symptoms.

HORTOPANU D. Pronosticul tifosului exantematic. [The Prognosis in Epidemic Typhus.] *Rev. Stiintelor Med.* Bucharest, 1947 Nov. Dec., v. 38 Nos. 11/12, 510-71. [15 refs.] French summary.

Case mortality from epidemic typhus in Rumania has fallen considerably for several decades and in 1946 it was below 10 per cent compared with 20 to 50 per cent in the last century.

During the recent war 463 cases were studied by the author and he believes that this improvement is due not to any epidemiological change as such, but to the better standards of life of the European populations, to progress in hospital organization and care of the sick, and markedly to the part played by sulphonamides and penicillin in reducing mortality attributable to complications.

Where nutritional and physiological states were low as was seen among refugees and prisoners of war the disease was of course more serious and the mortality higher. In famine typhus it has exceeded 20 per cent.

In a table, the author shows that a very important factor in causing death during typhus is the age of the patient. In his own records, 31 per cent of deaths occurred in those over 40 years and 50 per cent in those over 50. The exceptional gravity of typhus in those past middle age is stated to be due to existing arteriosclerotic lesions, which contribute to the serious complications.

of the disease itself, this arteriosclerosis is localized in just those organs in which the acute local lesions of typhus are to be found, *e.g.* the myocardium, brain and kidneys. The author, describing typhus as a "*maladie essentiellement artériolaire*", suggests that "the prognosis of epidemic typhus is inscribed on the patients' arteries". He regards a rising blood urea as an important sign in diagnosis and prognosis.

The prominent sequelae of epidemic typhus according to the author, are cerebral lesions, amputations for gangrene of the limbs, myocarditis and permanent mental disabilities, but in his experience such sequelae are not common and rarely exceed 1 per cent.

ANIGSTEIN L, WHITNEY, Dorothy M & BENINSON, J. Inhibition of Typhus and Spotted Fever in Guinea Pigs by Intradermal Inoculation of Antiorgan Sera and of certain Normal Sera. *Texas Reports on Biol & Med* 1948, v 6, No 1 87-96 [15 refs]

The serum of rabbits which had been inoculated with the spleen and bone marrow of guineapigs contains antibodies against these organs, and is called antiorgan serum. An area of the skin of each of several guineapigs was infiltrated with this serum and after two hours the centre of the area was inoculated with brain substance of guineapigs infected with typhus and "spotted fever" [Rocky Mountain spotted fever]. Evidence of active infection was usually absent except for a few animals which suffered from greatly attenuated attacks. The serum of normal rabbits occasionally caused an attenuation of infection in guineapigs inoculated in similar conditions. The interpretation of the barrier effect produced by the antiorgan serum is discussed and it is suggested that the production of a macrophage reaction by the serum may play an important part. The authors state that they can offer no suggestion as to the possibility of applying the results of their experiments to the prevention or treatment of typhus infections. The original paper should be consulted by those interested in the problem of the protective action of antiorgan sera.

ANIGSTEIN L, WHITNEY, Dorothy & BENINSON J. Inhibition of Typhus and Spotted Fever by Intradermal Inoculation of Antiorgan or certain Normal Sera. *Proc Soc Exper Biol & Med* 1948, Jan v 67 No 1 73-4. This is an abbreviated form of the above paper.

PLOTZ H, BENNETT B L, WERTMAN, K, SNYDER, M J & GAULD R L. The Serological Pattern in Typhus Fever. I. Epidemic. *Amer J Hyg* 1948, Mar v 47 No 2, 150-65, 2 figs [14 refs].

This important paper contains the substance of four confidential reports submitted in 1944 to the Surgeon-General of the U S A Army. Most of the work described was done by Col Harry Plotz, whose death in 1947 is deeply regretted. A detailed study was made of serological reactions on sera collected every two days from 32 confirmed cases of epidemic typhus fever treated at Caro in the winter of 1943. In attempts to recover rickettsiae from 23 of the patients, 21 strains of epidemic rickettsiae were isolated.

Strictly specific epidemic and murine antigens were prepared from yolk-sac rickettsial cultures by a modification of Craigie's method, in which the soluble non-specific antigens were removed by ether treatment combined with repeated

washing in saline of the rickettsiae deposited by centrifugation. The suspensions were preserved by the addition of formal to 0.2 per cent. Details of the technique employed are given in full for the first time.

The washed antigens gave no reactions with sera of patients or guinea-pigs convalescent from Q fever Rocky Mountain spotted fever hantennae fever, scrub typhus, and various other infections.

The antigens, after titration, were employed in a systematic series of complement fixation and rickettsia-agglutination tests of which complete details are given in the paper.

The following extract from a table shows the average titres observed at various stages of the illness.

| Day of Illness | Complement Fixation (Epidemic antigen) | Rickettsia-Agglutination | |
|----------------|---|--------------------------|------------------|
| | | (Epidemic antigen) | (Murine antigen) |
| 2-5 | 0 | 10 | 0 |
| 6-7 | 5 | 40 | 10 |
| 8-9 | 20 | 320 | 60 |
| 10-19 | 640 | 10,240 | 1,280 |
| 20-30 | 320 | 2,560 | 640 |
| 31-60 | 80 | 640 | 80 |

Titres for the complement fixation tests with murine antigen are not shown in the table, but from the complete data it appears that they were much lower than those with epidemic antigen except in one case in which they remained the same till the 14th day on which both were 1-40.

Complement-fixing antibodies of epidemic typhus usually appeared about the 6th or 7th day. In every case they were present before the 16th day.

Rickettsial agglutinins appeared earlier with epidemic antigens, no negative reactions were ever observed after the 7th day.

By both tests differentiation between epidemic and murine typhus was always possible. The chief value of the agglutination test was the earlier appearance of positive reactions, but there was a greater degree of cross-reaction than with the complement fixation test, with which in 18 cases the reaction against murine antigen remained negative throughout the illness, and in only four cases did the titres exceed 1-40.

With the Weil-Felix test (O119) a titre of 1-80 was reached in 26 cases by the 8th day and in the rest by the 11th day but, of course the test did not help in differentiating epidemic from murine infection.

John W. D. Meyer

SCOVILLE, A. B., JR., BENNETT, B. L., WERTMAN, H. & GAULD, R. L. The Serological Pattern in Typhus Fever. II. Murine. *Amer J Hyg* 1943, Mar., v 47 No. 2, 168-78 2 figs.

This paper is complementary to the preceding one. It contains the results of serological tests carried out in the same way on sera obtained from 13 patients during an outbreak of murine typhus in September 1944 in Tennessee. Murine rickettsiae were isolated from eight of the patients.

The results obtained, *mutatis mutandis*, were generally similar to those reported in the preceding paper except that the differential diagnosis between epidemic and murine typhus could not be made so early a stage.

The murine rickettsia-agglutination reaction was still negative in four of the ten patients tested on the 5th and 9th days, but no negative reactions occurred after the 9th day.

The murine complement-fixation reaction with washed antigen was still negative in 12 cases in tests carried out on the following days of the illness — 10th, 11th (3 cases), 13th (5 cases), 15th 16th and 19th day

With the non-specific soluble antigens the complement-fixation reactions became positive at an earlier stage in most cases

The Weil-Felix (*OX19*) reaction was positive on or before the 7th day in all of the six cases in which early tests were made. No negative reactions occurred after the 9th day. The *OX2* reaction became positive considerably later or remained negative, the titres were always much lower than those with *OX19*

The authors state that "Differentiation of epidemic and murine typhus fever can be made by complement-fixation or rickettsia-agglutination if highly purified antigens are used"

[If this statement implies that the differentiation can always be made by either of the two tests it seems to need qualification in view of the possibility that all strains of rickettsiae causing epidemic and murine infection may not give the same reactions as the strains dealt with by the authors. The delay in appearance of the specific complement-fixing antibodies is a drawback and it seems likely that the simple rickettsia-agglutination test with purified rickettsiae will hold the field as the best routine test for use in the differential diagnosis of the typhus fevers]

This, and the preceding paper should be read and kept for reference by every worker on the serology of the typhus fevers

John W D Megaw

SOMAN, D W A Study of Weil-Felix Reaction in the Diagnosis of Typhus Fever in Bombay *Indian Med Gaz* 1947, Nov, v 82, No 11 649-53 [17 refs]

The positive reactions observed in several groups of persons tested by the Weil-Felix method are summarized in the table which has been prepared from the material supplied in the paper

Numbers of Positive Weil-Felix Reactions Observed

| | <i>Proteus OX19</i> | | | <i>Proteus OX2</i> | | | <i>Proteus OXK</i> | | |
|---|---------------------|----------------------|---------------------|--------------------|----------------------|---------------------|--------------------|----------------------|---------------------|
| | 1-50 | 1-100 to 1-250 | 1-500 or over | 1-50 | 1-100 to 1-250 | 1-500 or over | 1-50 | 1-100 to 1-250 | 1-500 or ove. |
| | 1 | 3 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| 500 sera sent for Wassermann test | 5 | 16 | 28 | 2 | 2 | 0 | 2 | 1 | 1 |
| 763 sera from febrile patients including typhus cases | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 0 | 0 |
| 185 sera from enteric group cases | 0 | 1 | 22 | 1 | 10 | 1 | 0 | 2 | 2 |
| 28 sera from typhus-group patients | | | | | | | | | |

It will be seen that there is no evidence of the occurrence of anamnestic rises in the Weil-Felix titre in cases of enteric-group fevers

In 23 of the typhus-group cases the reaction was of the *OX19* type in eight of these, guinea-pig inoculation was carried out and *Rickettsia mooseri* is said to have been isolated from two of the patients in four other cases the animals gave a febrile reaction and in two there was no reaction

In two cases the reaction was of the *OX2* type serum from one of the patients was inoculated into a guinea-pig, with a negative result

In three of the cases the reaction was of the *OXK* type and from each of the patients *Rickettsia orientalis* is said to have been isolated by mouse inoculation

[The author like most other observers in India, seems to regard it as axiomatic that the occurrence of a *Proteus* OX19 type of agglutination indicates sea-borne murine typhus and excludes tick-borne typhus. PIOTIS *et al.* found that many cases of the tick-borne Rocky Mountain spotted fever gave an agglutination response of the OX19 type, and that the complement-fixation test was needed to differentiate the disease from louse-borne and flea-borne typhus (See, for example this *Bulletin*, 1945 v 42, 606.)] *John W D Meqaw*

CALERO C. Outbreak of Typhus of the Murine Type. First Report from the Isthmus of Panama. *Amer J Trop Med.* 1948, Mar v 28, No 2, 313-21 [22 refs.]

Since 1932, sporadic cases of murine typhus have been diagnosed in the Isthmus of Panama at the average rate of three each year.

Between January 15 and February 5 1947 there was an outbreak of 13 cases in the city of Panama. All the patients had worked in, or visited, a food store in which dead rats were found shortly after the occurrence of the first case. The cause of death of the rats was not ascertained.

Complement fixation and rickettsia-agglutination tests strongly supported the diagnosis of murine typhus. *John W D Meqaw*

RIGHTS, F. L. & SMADAL, J. E. assisted by Elizabeth B JACKSON. Studies on Scrub Typhus (Taisugamushi Disease). III. Heterogeneity of Strains of *R. tsutsugamushi* as demonstrated by Cross-Vaccination Studies. *J E par Med.* 1948, Apr 1 v 87 No. 4 339-51 [28 refs.]

It has already been found that animals which have recovered from infection with one strain of *Rickettsia tsutsugamushi* (*orientalis*) are immune to all other strains of the organism although striking differences have been shown to occur in the antigenic structure of the various strains when they are tested by complement fixation, serum protection, and toxin antitoxin tests.

In the present study the authors have found that Swiss mice inoculated with vaccines made from the tissues of rats infected with various strains of *R. tsutsugamushi* usually became protected against homologous strains but often remained susceptible to infection with certain heterologous strains. Examples of the degree of protection conferred by vaccines of different strains are shown in the table.

| Strains of Vaccines | Degree of Protection Conferred against Challenging Strains | | | | |
|-----------------------------|--|------|---------|--------|-----------------|
| | Imphal | Karp | Kostrul | Mit 21 | Volner (Malaya) |
| Imphal (India Burma border) | ++ | + | + | 0 | -- |
| Karp (New Guinea) | + | ++ | + | 0 | + |
| Kostrul (New Guinea) | ++ | - | ++ | 0 | +- |
| Mit 21 (New Guinea) | ++ | +- | + | +- | 0 |

++ means Immunity index 2.5 or above + means index 1.5 to 2.4
+- means index 0.5 to 1.4 0 means index below 0.5

Remarkable results obtained were —(1) Vaccine made from Mite 21 strain gave little protection against infection with the same strain, but good protection against the Imphal strain, and (2) None of the four vaccines protected the mice against infection with the Seerangayee strain.

In spite of the obvious antigenic differences, the authors do not think it desirable to "indulge in taxonomic speculations regarding division of the subgenus *R tsutsugamushi*".

The following comment is given in the authors' own words to illustrate the need for an agreed nomenclature of the typhus rickettsiae — "It may be noted that while cross-immunity is exhibited by animals which recover from infection with *Rickettsia prowazeki* and *R typhi*, or from infections with *Dermacentor rickettsi* and *D coroni*, nevertheless, vaccines prepared against one member of the pairs of agents afford comparatively little protection against the other" [Some readers are sure to be puzzled by the last three of these names which refer respectively to the rickettsiae of murine typhus, of Rocky Mountain spotted fever, and boutonneuse fever "*R coroni*" is, of course, a misprint for *R coroni*]

JOLGOPOL, Vera B. **Histologic Changes in Rickettsialpox.** Amer J Path 1948, Jan, v 24, No 1, 119-33, 10 figs on 4 pls

A detailed description is given of the histology of the initial lesion, the maculopulo-vesicular rash, and a lymph node, as observed in biopsy material from patients suffering from rickettsialpox.

The initial lesion closely resembled the eschar of scrub typhus, both in its histology and naked-eye appearance but it was more superficial and the vascular changes were less severe. Perivascular infiltrates were seen, but plasma cells were absent and mast cells were more numerous than in the eschar of scrub typhus.

The rash was similar in its microscopical features to that of other rickettsial diseases except that the cell infiltrates were much more profuse. The vascular changes were similar to, but less severe than, those of scrub typhus. The occurrence of vesicles in the spots is regarded as a unique feature of rickettsialpox among the rickettsial diseases.

The only evidence of damage to the lymph node was the presence of mast-cell infiltration of the lymphoid tissue, there was no necrosis of the lymph node such as has been described as occurring in scrub typhus.

PLAGUE

WYKKE-GRIFFITH, G. Pneumonic Plague in Rangoon. *Lancet*. 1948, Apr. 4, 625-7. [25 refs.]

In Burma plague has long been endemic, and the same of course applies to Rangoon. Rangoon, however, has no record of a series of cases of pneumonic plague such as the present outbreak. It occurred in September and succeeded an earlier bubonic epidemic in spring. There were 18 deaths, but suspicion of the nature of the disease did not arise until the occurrence of case 11 which was the first notification to the health authorities. The epidemic had much the same course as other epidemics and much the same nature—high fatality rate and highly restricted area of diffusion. The epidemic rapidly burned itself out. An interesting point is raised in discussion—the assumption that pneumonic plague is very infectious. That assumption is questioned and, certainly in the present epidemic, the conclusion might be reached that “the disease is not particularly infectious.” Preventive measures are rightly to be taken in spite of the fact that “theoretically pneumonic plague is easily controlled.” The author continues—“The incubation period is relatively short hence very few contacts will become cases after a week’s quarantine. There is a distinct non-infectious phase lasting twenty-four to forty-eight hours after the onset of clinical illness. Immediate isolation during this phase of all cases of suspicious illness will effectively abort the outbreak.”

CHOLERA

KHALLI Bey M. The Defence of Egypt against Cholera in the Past, Present and Future. *J. Roy. Egyptian Med. Ass.* 1947 Dec. v. 30 No. 1, 608-55. [12 refs.]

This address, which was delivered on 31st October 1947, was doubtless given to a special audience. It has particular interest at the present time as forecasting a possible or probable appearance in May 1948 of the epidemic of cholera which has ravaged Egypt anew after a long interval of freedom. For the prevention of this danger much evidently depends on the public health authorities. There are many details of historical interest set out very emphatically. Even more important than the views expressed as to the origin of the present epidemic, which follow current lines, is the declaration that reform is needed in the public health administration and the quarantine

administration of Egypt The Egyptian Government has acted vigorously in providing funds for hygienic necessities There is obvious need to provide a pure water supply from tube wells to three-quarters of the Egyptian villages, and the experience of the value of such a supply has been amply demonstrated in the present epidemic by the comparative immunity from cholera of urban populations provided with an urban type of water supply

The old questions of the danger of the Mecca pilgrimage for Egypt according to the time of year at which it takes place are discussed Evidently the institution of the quarantine station of El Tor has justified itself It is now necessary with air travel, to have a new convention to replace that of 1944, for the protection of Egypt is considered to be equivalent to the protection of Europe

RAYNAL J H Quelques mots sur le choléra en Egypte (automne 1947) [A Note on the 1947 Cholera Epidemic in Egypt] *Méd Trop* Marseilles 1947 Nov-Dec v 7 No 3 470-74 1 chart & 1 map W F Harvey

GOHAR, M A & MAKKAWI, M Some Observations on the Cholera Vibrio Isolated from the 1947 Egyptian Epidemic *J Roy Egyptian Med Ass* 1947, Nov, v 30, No 11, 525-9

"1 The morphology, cultural characters, resistance and pathogenicity of the Korain strain of cholera vibrio correspond to a large extent to those of the classical strains, except perhaps that the vibrio is not very markedly curved and rather short

"2 Serologically it was found identical with the Inaba strain which is known to be the most prevalent strain in certain parts of India

"3 Its short life inside dates is apparently due to the acidity produced by the fermentation of the carbohydrates present abundantly in them Ten per cent lemon juice is enough to kill it almost instantaneously "

GOHAR, M A & MAKKAWI, M Potassium Tellurite in the Isolation of the Cholera Vibrio *J Roy Egyptian Med Ass* 1947, Nov, v 30, No 11, 556-61

The common enrichment method of isolation of the cholera vibrio by inoculation of stools in alkaline peptone water, incubation for 6 to 8 hours and then plating on alkaline agar may delay the isolation, or even render it more difficult than direct plating Several experiments were undertaken to determine the meaning of this in terms of antibacterial action or overgrowth by other organisms, such as *Bact alkalisgenes*, *Bact coli* and enterococcus Antibacterial action was disproved and overgrowth incriminated In fact the suggestion is made that it is the possession of an intestinal flora with the power of overgrowth that may determine infectivity for the individual

The main endeavour was to find a selective bacteriostatic substance to incorporate in the nutrient medium, which would inhibit the growth of *Bact alkalisgenes* and *Bact coli*, with less or no effect on the cholera vibrio The substances tried were potassium tellurite potassium and sodium selenite violet, mercurochrome, methylene blue, thionin, basic fuchsin, brilliant green, crystal violet, neutral red, eosin and flavin Of these, potassium tellurite proved the best when added to alkaline peptone water in a dilution as great as of 1 in 50,000 This has little effect on the cholera vibrio and the enterococcus, but has

bacteriostatic action on the other organisms. The enterococcus gave little trouble in the isolation of the cholera vibrio. Thus this method of enrichment "is recommended for the examination of convalescents, contacts, water and other suspected materials."

W. F. Harvey

GOMAR, M. A. & MARKAWI, M. Cholera in Egypt. Laboratory Diagnosis and Protective Inoculation. *J Trop Med & Hyg* 1948, May v 51 No. 5 95-9

One or two points regarding the recent outbreak of cholera in Egypt are brought out in this and the several papers which have appeared on the subject. It "created a state of terror almost amounting to panic." The authors have devised a valuable method for reducing labour and saving time in the laboratory by illuminating the contaminating overgrowth of the "true cholera vibrio by *Bact. alkaligenes*. This method has been described above (see also this Bulletin 1948 v 45 600) and depends on the motility of the vibrio, its aerobic character and the inhibitive action of potassium tellurite. The "true cholera vibrio is truly a highly selected organism.

A feat in mass vaccination was accomplished. General vaccination of a population amounting to nearly 20 million people was achieved in Egypt probably for the first time in the history of this disease. One dose of 8,000 million organisms was given to everybody, very few people received 2 doses. As bacteriologists, the authors are cautious in their deductions. It would be rash to try and draw any conclusion as to the value of general vaccination adopted in this epidemic.

An extensive research was conducted into the viability of the cholera vibrio on various articles of food and clothing. A high correlation between the time of collection of dates and the time of occurrence of a cholera epidemic is commented on.

TAKAMAE, S. J. W. Een Serologische en een colloïd-chemische reactie ter onderscheiding van cholera-en El Tor vibriën. [A Serological and Colloïd-chemical Reaction for Cholera and El Tor Vibrios.] *Nederl. Tijdschr v Geneesk* 1948 May 8 92 () No 19 1370-75 English summary

With the discovery of an El Tor vibrio strain in Celebes the El Tor question as the author says, was infused with new life. Regulation tests for the true cholera vibrio were reviewed: haemolysin production—a bad guide, not an production—unsuitable in practice; acetylmethylcarbanol formation—no differential value; serum reactions—not distinctive. He is speaking, especially of the differentiation of the haemolytic El Tor vibrio from the true cholera vibrio and of antigenic analysis. This leads up to his introduction of a colloïd-chemical test. A serum reaction is regarded as occurring in two phases: the first of fixation of antibody or sensitization and the second of flocculation by sodium chloride or saline as electrolyte. He has used as serum the Damang O-antiserum which is probably identical with the Hikojima or intermediate type. A number of electrolytes were tested and of these sodium carbonate Na_2CO_3 \cdot $\frac{1}{2}\text{H}_2\text{O}$ was the most suitable while sodium bicarbonate was unsuitable. In this test a high-titre disinfectant free cholera antiserum was diluted 1 in 200 with 0.3 per cent sodium carbonate, and to 1 was added a concentrated vibrio

suspension in distilled water. The mixture is well shaken and it should be found that cholera vibrios remain consistently inagglutinable while El Tor vibrios flocculate completely and are deposited. If the soda solution is set up in series 0.1, 0.2, 0.3, 1.0, 2.0, 5.0 per cent, it is found that up to 0.2 per cent both vibrios flocculate out, above 0.2 per cent only El Tor still flocculates, but above 0.5 per cent the El Tor also remains in consistently stable suspension.

The second test depends on the replacement of the serum by chemical solutions alone. A few drops of concentrated vibrio suspension in distilled water are added now to the solution previously found unsuitable, namely, a 0.5 per cent NaHCO_3 , and after 15 minutes an equal volume of 0.5 per cent mercuric chloride is added to the mixture. Now the phenomenon is reversed: cholera vibrios flocculate immediately, while El Tor vibrios remain in uniform suspension.

GREPPIN, J. Mission médicale suisse en Egypte [Swiss Medical Mission in Egypt] *Bull. Internat. Services de Santé des Armées* Liège 1948, Mar-Apr, v 21, Nos 3/4, 53-61.

Switzerland through its Red Cross organization acted swiftly and philanthropically in offering its help to the Egyptian Red Crescent to control the outbreak of epidemic cholera. The offer was gratefully accepted and the party of doctors, technicians and hospital sister got to work at the small 25-bed hospital of Kafr-el-Zayat in the Delta region between Cairo and Alexandria. They found 186 patients in the hospital area. Patients commonly arrived comatose, dehydrated and cold. Treatment for shock consisted of the administration intravenously of 5 to 10 litres of glucose-saline in the 24 hours. Hypertonic saline or bicarbonate of soda solution were required for acidosis, while hypoproteinaemic patients received infusions of plasma.

The average case-mortality rate in this hospital has been calculated at 30 per cent, contrasting with that of Egypt generally, which was 50 per cent.

A laboratory was attached to the hospital, and although equipment was short much good work was done in isolating vibrios. A very active cholera phage was isolated, which caused lysis in the high dilution of 10^{-10} and was used to differentiate the Egyptian cholera strains from the El Tor vibrio and non-pathogenic strains.

Three villages and the population of Kafr-el-Zayat were treated with DDT, of which the Swiss had 1,000 kgm of 50 per cent powder. This was used in 2 per cent aqueous suspension (1 per cent of the active ingredient) for the walls of houses and sprayed by motor pumps under pressure of 20 atmospheres. Its lethal effect was observed not only on flies, but on lice, fleas, bugs, cockroaches, wasps and mosquitoes. The anticholera mission returned to Switzerland on 17th December.

HALAWANI, A. & OMAR, A. A. Effect of Copper Sulphate on *Vibrio cholerae*. *J. Roy. Egyptian Med. Ass.* 1947, Nov, v 30, No 11, 547-52.

'1 Copper sulphate is lethal in dilutions ranging from 20-45 parts per million to *Vibrio cholerae* in concentrations ranging from 10 to 1,000 million per cc of Nile water.

"2 We believe that copper sulphate has its place in the prevention of cholera especially as it is used in this country in the eradication of snails in water canals."

sub-inoculation of the guineapig's blood or brain into a rat or mouse. The tick-borne spirochaetes vary in their receptivity to the guineapig. *Sp. hispanica* (sic) of North Africa always produces a patent infection. The South American strains—*Sp. [Trep.] tenuicollis* and *Sp. [Trep.] neotropicalis* are completely refractory. It is concluded that the susceptibility of the guineapig provides a good biological test. [This test would be of little value in tropical Africa, where the researcher and his co-workers (this *Bulletin* 1948, v 45 88) showed that both types of spirochaetes were occasionally able to infect guineapigs. A better method of differentiating these African strains is to observe their behaviour () in monkeys (*duttoni* is fatal, *recurrentis* is not) and (b) in mice (*duttoni* causes persistent infections, *recurrentis* lasts for 2 or 3 days only).]

CONSTANTINESCU G & IONESCU R. Contribuțiuni la studiul forme meningeale în febra recurentă. [Observations on the Meningeal Form of Relapsing Fever] *Rev. Stiintific Med. Bochart.* 1947 Nov-Dec., v 35 No. 11/12, 503-6. French summary (4 lines)

Of 285 cases of relapsing fever studied in 1945 12 were of a meningeal type. The cerebrospinal fluid was usually clear and not under pressure, and sometimes showed xanthochromia or gross haemorrhage. In no case could the causative organism be demonstrated in the cerebrospinal fluid. Meningeal signs appeared at the first onset of fever. They cleared up during the apyrexial period and did not reappear during the next onset of fever. The nervous symptoms were unaffected by arsenical treatment.

MUIR, E , KIRWAN, E W O G ADAMS, A R D Symposium on Leprosy. Recent Advances in the Treatment of Leprosy [MUIR] *Trans Roy Soc Trop Med & Hyg* 1948, Mar, v 41, No 5, 575-82 The Eye in Leprosy [KIRWAN] *Ibid* 583-90, 2 coloured figs on pl [16 refs.] Three Cases of Leprosy treated with Diasone [ADAMS] *Ibid* 591-4 Discussion 595-9 [MANSON-BAHR, P MAC ARTHUR, W , COOKE, W E BROWNLEE G , CHESTERMAN C C , GRAY W H , MUIR, E , KIRWAN, E W O G ; ADAMS, A R D]

The opener of this discussion dealt almost entirely with trials of the new sulphone drugs, promin, diasone, promizole and sulphetrone of Burroughs Wellcome & Co on the lines of his earlier papers on the first two arrest of the disease may be expected in the majority of lepromatous cases in about five years Promizole was found less effective by U S A workers and has been given up by them, as it is difficult to make, expensive and it presents no advantages except that it is slightly less toxic than some Of greater interest is the statement that early reports on the use of sulphetrone indicate that it is less toxic and gives quicker results than the other sulphones yet tried All of them require hospital treatment to enable resulting anaemia to be detected and treated with iron and liver preparations, to which Muir advises the addition of vitamin B in the form of yeast In patients subject to reactions, small doses should first be given, such as 0.3 gm of diasone or 0.5 gm of sulphetrone, both orally every other day, cautiously increased to 2 gm on alternate days This point may be reached in a few weeks or it may take many months In early uncomplicated cases the dosage may be increased more rapidly A fall of haemoglobin below 70 per cent is an indication to stop the drug, as is the occurrence of reactions. Destructive effects of sulphones on lepra bacilli are only well marked in the neighbourhood of capillary blood vessels DAVEY has recently reported from Nigeria some lepromatous cases in which the lepromin test has changed from negative to positive within 5 to 10 months under sulphetrone Tuberculoid cases, with few lepra bacilli, do not apparently respond as well to sulphones. Improvement occurs in most lepromatous cases in 2 or 3 years Greatly increased accommodation and medical staff in resident institutions will be necessary to enable the prolonged sulphone treatment to be carried out in all lepromatous cases, but with the promise in time of greatly reduced numbers of highly infective cases

KIRWAN spoke on eye infections in leprosy from a large experience in Madras and gave a table of their frequency varying from 42 to 100 per cent They occur in neural cases as a result of the exposure of the cornea owing to muscular paralysis, and in lepromatous cases owing to infection through the blood stream The original paper should be consulted for detailed description Treatment is difficult, but penicillin is advised locally for conjunctivitis The slit lamp with the corneal microscope and the electric ophthalmoscope are essential for diagnosis

ADAMS reported three lepromatous cases treated with diasone with marked retrogression of the skin lesions but no obvious diminution of the bacilli MACARTHUR spoke on misconceptions regarding the incidence of leprosy during Biblical and mediaeval times due to too literal interpretations of words which in early times had a wider and more general application than they now have

BROWNLEE spoke on the toxic effects of sulphones and described the resulting anaemia as hypochromic at first, but later of the nutritional type The latter

he attributes to a change in the intestinal flora which cuts down the biosynthesis of vitamins of the B-complex group. Yeast treatment is indicated in such cases.

AYCOCK, W. L. A Proposed Study of Conjugal Leprosy with reference to Contagion and Hereditary Susceptibility. *Internat. J. Leprosy* 1948, Jan.-Mar. v 16 No. 1 1-8, 2 charts.

This paper discusses the possible light thrown by the incidence of conjugal infections on the difficult question of the relative influences of contagion and hereditary susceptibility. The following are the main points in a largely theoretical discussion. The occurrence of several cases in one family may be due to either contagion or heredity. The infection of twice as many males as females is more in keeping with the Mendelian operation of hereditary susceptibility. Data on conjugal leprosy might help to decide between susceptibility and prolonged exposure to contagion, but age susceptibility complicates the question. The rarity of conjugal leprosy allows of comparative studies of regional, racial and familial factors. More frequent child infections may be due to greater exposure to infection. Consideration of both the interval after conjugal exposure and the age at which the disease occurs would make it possible to distinguish between prolonged exposure and familial susceptibility as the probable determinant in conjugal infection. Reference is made to a previous paper by the author and Gordon (this Bulletin 1948, v 45 188) on leprosy in veterans of American wars, which showed that Spanish American War veterans from non-leprosy regions acquired their initial exposure on military service. In World Wars I and II veterans from foci of the disease were found to be infected during or shortly after their military service and developed their disease within a few years of beginning their service, whereas Spanish War veterans developed theirs on an average of 23 years after their military service and at an age 20 years later than the former. It is therefore anticipated that conjugal cases may show a similar pattern of two groups of development of the disease, either soon after marriage or at a much longer interval, and at later ages. The latter are likely to have contracted the disease from their spouses, the former through previous exposure in their own families. Further studies of conjugal cases on these lines are indicated. A suggested table for notes on cases of conjugal leprosy is given.

In this important paper Mitsuda, or lepromin, reactions on 601 patients in 1941 are tabulated under the types of "uncharacteristic" and tuberculous and the subsequent variations in the reactions and the evolution of the cases are examined. The sixteen tables should be studied in the original, but the following are the conclusions arrived at. Of 216 uncharacteristic cases 60 were

Vol 45, No 8]

Leprosy

negative in 1941, 41, or 68.3 per cent, of which had developed into the lepromatous type by 1946. Of 139 positive cases, 33 or 23.7 per cent, became lepromatous. A much smaller proportion of strongly positive (3 plus) became lepromatous than of weak (1 plus) cases. Nevertheless, the general assumption regarding the prognostic value of the test is by no means universal. Among 685 tuberculoid cases 592, or 86.4 per cent, gave positive reactions, 79, or 11.5 per cent, negative and 14, or 2 per cent, doubtful reactions. Only 17, or 2.9 per cent, of the positive cases developed into the lepromatous type, but of the negative cases 29, or 36.7 per cent, became lepromatous, together with 1 of the 2 doubtfully reacting ones. The prognostic indications of the test were thus more accurate in the tuberculoid cases, but not absolute. In some cases of both types a change occurred from a positive to a negative type and *vice versa*. In 3 of the latter, the lepromatous type nevertheless developed, among those changing from positive to negative, lepromatous transformation occurred in all except one patient.

Box, Louise A. **Benadryl in Acute Lepra Reactions.** *Hawaii Med J* 1948, Mar-Apr, v 7, No 4, 303-4

The author reports on a trial of an anti-histamine drug, Benadryl (B dimethylaminoethyl benzhydryl ether hydrochloride) in the allergic reactions of leprosy. The 9 treated cases include 3 with acute lepra reactions of spontaneous occurrence, 4 with acute lepra reactions apparently precipitated by promin treatment, and two with "major tuberculoid" reactions. The effects were compared with histories of previous reactions, of which it was not always possible to get reliable accounts. An average dose of 50 mgm is given three times a day and continued from a few days to several weeks in accordance with the length of the reaction. The three spontaneous acute reactions appeared to respond well, as did the four which had followed promin treatment, but the two major tuberculoid ones gave equivocal results. The patients had no pain and no new lesions developed during a reaction. The author is cautious in coming to conclusions, but thinks further investigation of anti-allergic drugs in the treatment of acute leprosy reactions is indicated.

CHANDY, P J. **Iodised Hydnocarpus Oil in the Treatment of Leprosy** *Leprosy in India* 1947, July, v 19, No 3, 72-9

The author reports on the treatment of 44 cases, most of which were lepromatous and bacteriologically positive, by iodized hydnocarpus oil prepared by the following method so as not to contain any free iodine. 36 grams of re-sublimed iodine are dissolved in 1 ounce of ethyl ester of hydnocarpus oil, this iodine ester is then poured into a one pound bottle containing 15 ounces of hydnocarpus oil. The contents are well shaken and the whole is then sterilized in an autoclave at 15 lb pressure for half an hour. Heat-proof glass bottles should be used. Injections are free from pain and as much as 10 cc can be injected intramuscularly at one site without induration or other trouble and without serious reactions. The injections were given once a week for two years, to a total amount of over 400 cc. Nodules flattened and in time disappeared, bacilli decreased and the majority of the cases became bacteriologically negative, especially those in which the organisms were not very numerous at first. The results were better than with Hydnocroal. A table shows details of the cases.

"For regulating the dose of the *hydnocarpus* oil it is not necessary to take into consideration the results of the sedimentation index. The treatment can very well be regulated by the clinical condition of the patient. The sedimentation index does not provide any additional information."

DE SOUZA LIMA, L. Tratamiento experimental de la lepra. [The Treatment of Leprosy] *Medicina*. Mexico. 1948 Mar 25 v 28, No. 332, 129-33.

The reason for calling this treatment experimental is not quite clear. The author states that *chanlmoogra* has a false reputation and that he has no belief in its efficacy for three reasons. 1. That good report of its use has been (in the Padre Bento Sanatorium) in tuberculous forms, yet in about 98 per cent. of 200 cases this disease retrogressed spontaneously and the remainder progressed even to mutilation in spite of the treatment. 2. That observation over 4 years of "two lots" [the numbers of patients are not given] of non-characteristic forms of leprosy one group receiving *chanlmoogra*, the other not showed that the same percentages were transformed into lepromatous, or tuberculous, or retrogressed in each group, so that the painful treatment with *chanlmoogra* had no effect and might just as well have been omitted. 3. That *chanlmoogra* did not influence the progress in a thousand cases under observation those of the lepromatous form which seemed for a time to improve relapsed again within a comparatively short period. *Chanlmoogra* preparations were given intramuscularly or intradermally in varied doses.

The author then relates his experiences with Promin, given intravenously each day starting with 1 cc. and increasing gradually to 5 cc. administration being for a fortnight, followed by a week's remission. Next, with Diasone given orally in doses of 0.33 gms. (0.33 gm. ?) daily for 6 weeks, followed by a rest for a fortnight. From these singly or combined, excellent results are recorded, even in cases of ocular leprosy. In ordinary cases infiltration was reduced, discoloration gave place to a normal skin, and biopsy search for bacilli showed steady reduction. At first Diasone seemed to aggravate the skin conditions, infiltrations became more swollen, lesions extended and fresh ones appeared, but they soon cleared up if the treatment was persisted with.

DAVISON A. R. Antimony in the Treatment of Leprosy. *Internat. J. Leprosy* 1948 Jan. Mar., v 16, No. 1 23-8, 15 figs. on 2 pls.

Experience at the Pretoria Leper Institution supports the view that antimony has the power of controlling lepra reactions and benefit erythema nodosum leprosum. Insulin is also being used, but the author has not yet decided which is the better treatment. The drug is also of value in tuberculous cases in the re-active phase and in neural cases which are developing new macules through having a lowered resistance. Fouladin is given in courses of ten intramuscular injections followed by a fortnight without treatment. Continued and intensive courses of antimony treatment were not beneficial. If antimony fails to build up resistance leumoth may be of use. The appearance of new lesions is an indication for stopping *chanlmoogra* treatment. Most of the cases were of the neural type but in three lepromatous cases antimony helped to render them free from bacilli. Antimony may also be of

use as an adjuvant to promin treatment Antimony is not a specific cure for leprosy, as failures have equalled the successes, and the treatment must be adjusted to every individual

ERFAN, M & TALAAT, S Demonstration of Schistosoma Ova in the Liver by Biopsy *J Roy Egyptian Med Ass* 1947, Dec, v 30, No 12, 663-4

The authors obtained liver biopsies in 41 cases of Egyptian splenomegaly. The biopsy was carried out under local anaesthesia by means of a small-calibre lumbar puncture needle, the tip of which is "debevelled to act as a trocar and cannula". The instrument is pushed 2 to 3 cm into the liver during full expiration, the trocar is withdrawn and a 10 cc Record syringe fitted tightly to the cannula. Suction is applied, the cannula is pushed in another 2 to 4 mm and withdrawn while suction is maintained. The puncture is sealed with collodion. The preliminary anaesthesia is obtained by infiltration of the skin, the pleura and peritoneal covering of the liver with a total of 10 cc of 2 per cent novocain solution.

The liver substance obtained is washed in saline and digested in a centrifuge tube with 5 drops of 4 per cent sodium hydroxide, the tube is warmed until digestion is complete, when the material is centrifuged and examined for ova.

Schistosome ova were found in 21 cases. 11 were *S mansoni*, 5 were *S haematobium* and in 5 cases, ova of both species were found. In 4 cases, *S haematobium* ova only were found in both liver and faeces specimens. In 7 of the 21 cases, faecal examinations were negative, but ova were found in the liver.

Ova were present in liver, faeces or urine in 39 of the 41 cases, which the authors state "practically disposes of the theory that hepatic bilharziasis is due to infection with male schistosomes".

In 19 of the positive cases having ova in the stools, the liver and spleen were enlarged.

In one case, ova were present in the liver although neither it nor the spleen was enlarged.

It is concluded that liver biopsy is a simple, safe and useful means of diagnosing hepatic schistosomiasis.

H J O'D Burke-Gaffney

LOVERIDGE F G, ROWS W F & BLAIR, D M. Schistosomiasis: the Effect of the Disease on Educational Attainment. *South African Med J* 1948, Apr 10 v 22, No. 7 260-63.

KISSEN (this *Bulletin* 1948 v 45 526) observed the deleterious effect of urinary schistosomiasis on the scholastic attainment of children in Transvaal schools. In Southern Rhodesia, school teachers in European Schools frequently suspect schistosomiasis as an explanation of forgetfulness and lack of concentration in some of their pupils, and it is striking how often this tentative diagnosis is confirmed by medical examination and parasitological investigation.

In the case of European children tests were made in two boys' schools which were generally comparable except that one gave an academic and the other a modern education. In general, the average intellectual standard was higher in the former.

"Presumptive" infections were diagnosed by a cercarial antigen skin test and proved infections were those afterwards confirmed by the finding of ova in the urine or stools or both.

A table indicates that in both presumptive and "proved" infections the schistosomiasis rate was significantly higher in the boys from the modern school the findings being 74 and 27 respectively from 91 boys, compared with 37 and 9 from 118 boys in the academic school. The statistical significance of these figures is shown.

In the case of African schoolchildren, an investigation was carried out on 365 pupils of both sexes in one school—those in 11 classes were grouped on school examination results into upper and lower halves in each class—a note was made of those who failed in the examination. The results are shown in a table from which it emerges that the "proved" infection rate averaged 50 per cent. Nevertheless, these did not represent the main constituent of the lower half of each class—indeed the infected children made a slightly better showing in "presumptive" and "proved" infections alike. For example only 30 per cent. of the pupils were regarded as being uninfected on the "presumptive" criterion yet more than half of them were in the lower halves of the classes. Again, only 44 of 82 pupils who failed in their examinations had schistosomiasis. On the other hand pupils with proved infections took 45 out of the 44 places comprised by the first four places in each of the 11 classes. An additional 9 members of this group gave presumptive evidence of infection, so that some evidence of schistosomiasis was present in 77 per cent. of the pupils who won all the top four places.

It appears that schistosomiasis had no adverse effect on the educational attainment of these African schoolchildren and, indeed, the infected children seemed to fare better than the uninfected.

While admitting that the reason for this difference between the European and African children is not clear the authors observe that the African child is exposed to schistosomiasis earlier in life than the European and that the disease is more chronic in him at school age. It also may be that one more helminth infection, added to an organism already perhaps overburdened with other parasitic or nutritional influences may make little difference to the general lowering of the level of scholastic attainment—but this does not explain the better performance actually observed in the infected children.

H J O'D Burke-Gaffney

FACIST E C. An Inquiry into the Ectopic Lesions in Schistosomiasis. *Amer J Trop Med* 1948, Mar 28, No 2, 15-69 1 fig. (64 refs.)

Ectopic schistosomal lesions have been reported with increasing frequency during recent years. Many among the American and Australian troops

engaged in the highly endemic schistosomiasis areas in the Philippine Islands acquired schistosomiasis, and among these ectopic lesions have been not uncommon. The subject is therefore one of current as well as of practical importance. In this paper the literature on the subject is reviewed in some detail, and the mode of origin of the ectopic lesions is critically examined. The author gives the following summary and conclusions, but the original should be consulted by those interested.

"1 Ectopic lesions in schistosomiasis are defined as those produced by immature or mature stages of schistosomes outside the portal-caval venous blood channels with their extension into the pulmonary arterioles. The lesions occasioned by the migration of young worms have been studied critically in experimental hosts but are not histologically described for man.

"2 Interpretation of the lesions produced by schistosomes in man or other definitive hosts requires background information on the usual route of migration of the larvae from the site of their entry into the body to their arrival in the intrahepatic portal vessel, the growth of the worms in this location, their subsequent passage against the venous blood current to the mesenteric venous radicles or vesical plexus where they mature and oviposition takes place, and finally the local and systemic tissue reactions to the presence of the worms in the body.

"3 Tabulation of published and other case histories of ectopic schistosomiasis, based on autopsy, biopsy, surgical intervention and substantial clinical data indicates that there are not less than 82 known cases with 86 separate sites where these lesions have been located. Twenty-one cases with 23 lesion sites are attributed to *Schistosoma haematobium*, 12 cases with 12 lesion sites, to *S. mansoni*, and 49 cases with 51 lesion sites, to *S. japonicum*. A majority of reported ectopic lesions in *S. haematobium* infection have occurred outside the brain and its blood vessels, a significant preponderance of those in *S. japonicum* infection have been in the brain, while those in *S. mansoni* infection are too few to show any significant anatomical predilection.

"4 The tissue reaction to schistosome eggs which escape from blood vessels into perivascular tissues is an acute inflammatory one in which histiocytes, epithelioid cells, giant cells, eosinophils, plasma cells and fibrocytes attempt to wall off the invading foreign body, with the eventual production of a pseudo-tubercle around each egg as a center. Nest [*sic*] of eggs were typically found within relatively circumscribed areas, so that each lesion consists of an aggregate of pseudo-tubercles forming a granuloma that varies in size from a pinhead to an orange. The smallest ectopic lesions have been found in the conjunctivae, the largest ones have occurred in the brain.

"5 From the time of entry of the metacercariae of the human schistosomes into the cutaneous venules, following exposure to infection, the worms are characteristically intravascular in their location. There are several records of ectopic location of the adult worms, one in the middle cerebral vein, one in the ophthalmic vein, one in a coronary artery, and larger numbers from gastric, splenic esophageal, hepatic and renal veins of heavily infected experimental animals. In no instance is there any evidence of local tissue reaction to the presence of the worms.

"6 Five separate theories have been adduced to account for ectopic lesions in schistosomiasis. (1) Metacercariae develop to adult worms, with subsequent oviposition, at or near the sites of penetration into the skin or mucous membrane, (2) a patent foramen ovale would provide a direct route from the inferior caval veins into the systemic circulation, (3) eggs may escape through the pulmonary capillaries and be deposited in distant arterioles, (4) adult worms may travel against venous blood flow into collateral vessels and on reaching the end venules deposit their eggs, and (5) the vertebral

One patient with a haemoglobin of 35 per cent. died and the reader is left to assume that one of their criteria of fitness for treatment, i.e. a minimum haemoglobin level of 50 per cent., was instituted after this mishap.

In successive paragraphs, they say (1) "It is also known that the drug is excreted in 2-3 days through the kidneys" and (7) "With the standard methods of treatment the drug remains in the body for a month on an average."

Five charts are given intended to show the number of days taken to produce ova free urine but it is impossible to correlate the numbers given in the text with those given in some of the charts. Nevertheless, their two-day course is worthy of extended trial and should be very valuable in hospital work.]

SAID EL AYADI M. Treatment of Bilharzia by the Oral Route. *J. Roy. Egypt. Med. Ass.* 1947 Vol., 30 No. 11 562-6.

Ten million of the population in Egypt suffer from chronic schistosomiasis. Parenterally administered trivalent antimony is unsuitable for mass treatment of the population for this infection. Methods of treatment with antimony by the oral route were investigated, attention being directed particularly to the avoidance of emesis, to the promotion of absorption of the drug from the intestine and to the establishment of the effective dosage of the selected compound.

Repodral (Fouadin) in 6.3 per cent solution was selected for trial. Tolerance to its administration by the oral route was found to be increased by giving the drug in small amounts at intervals of $\frac{1}{2}$ to 3 hours on an empty stomach. Beginning with 4.5 ml., divided into 5 doses during the first day the amount was increased daily until on the 6th day 8.2 ml. were given the gross dosage in this period was 40.0 ml. There was no vomiting as a result of the treatment. [The number and the weight of the persons used in this experiment are not stated.]

Of the substances (unspecified) examined to promote absorption of antimony from the gut riboflavin in doses of $\frac{1}{2}$ to 3 mgm. was found "to produce the desired effect. Its action is likened to that of vitamin D on calcium, and vitamin C on iron, absorption."

Dogs were injected with a total of 0.4 ml. of Repodral per kgm. of body weight as described by HALAWANI and ABDALLAH (this *Bulletin* 1947 v 44 230). On examination 24 hours after the last injection, the antimony content of the liver was found to be about 3.5 mgm. per cent. This amount of antimony is (assumed by the authors to be) that in human livers found by the above-mentioned workers to be lethal to schistosomes in 12 of their 15 patients. The oral dosage necessary to produce this level of antimony in the livers of dogs was 7 ml. per kgm. body weight.

Four *Cercopithecus griseo-nubilis* or *griseonubilis* were infected with *Schistosoma haematobium* eggs appeared in their stools after 84 days. Two of the monkeys were treated with riboflavin and Repodral (2 ml. per kgm. divided into 6 doses over three successive days). A third monkey was treated with 0.6 ml. per kgm. for two doses only. The fourth was untreated.

The number of ova in the stools of the three treated monkeys gradually decreased over a period of a month the proportion of dead ova steadily increased, until after 10 to 15 days no living and only an occasional dead ova was found. After 23 days no more ova were found in the two fully treated monkeys there were scanty living ova from the incompletely treated monkey the control still produced living ova. The incompletely treated monkey was then given 0.34 ml. per kgm. of Repodral no ova were subsequently

ound over one week's daily observation. It is concluded that oral treatment of schistosomiasis with 2 ml Repodral per kgm of body weight, with riboflavin, is curative. 0.66 ml per kgm is not curative, 1 ml per kgm may be so.

A R D Adams

HALAWANI, A, NEWSOME, J & WOOTTON, I D P. Miracil D. Investigation of Blood Levels after a Single Dose. *J Roy Egyptian Med Ass* 1947, Dec, v 30, No 12, 656-62, 2 figs (1 folding)

Miracil D or Nilodin is a new remedy recommended for the treatment of schistosomiasis [this *Bulletin*, 1948, v 45, 526]. In this study, 400 mgm were given as a single oral dose to each of 22 male Egyptian patients. The blood concentration was measured by the method of LATNER, COXON and KING [this *Bulletin*, 1948, v 45, 96] with slight adaptations. In patients with normal kidney function, the blood level rose to a maximum at 12 hours and fell almost to zero by 24 hours. The maximum ranged from 60 mgm to 400 mgm per 100 ml. In patients with a renal clearance of less than 50 per cent, the 12-hour blood concentration ranged from 140 to 350 mgm per 100 ml. and the concentration was often still high at 24 hours. Impaired kidney function causes the blood level to be higher and more sustained than it is in normal persons. In order to maintain a persistent high level in the blood, it is recommended that miracil should be given at intervals of 12 hours, with patients who have poor kidney function it may be enough to give it every 24 hours.

GELFAND, M. Cysticercosis of the Brain in the African of Rhodesia. *East African Med J* 1948, Mar, v 25, No 3, 110-12

Between 1940 and 1945, the author found seven cases of cerebral cysticercosis in 2,148 autopsies in Salisbury Native Hospital, Southern Rhodesia. There were also three cases of cysticercosis of the heart, one of which also showed the cerebral form. The cysts were commonly seen in varying numbers over the frontal and parietal lobes and occasionally in the occipital region. In two cases, they occurred on the cerebellar surface. The cysts were always found on the brain surface, but never in its substance.

The Mashonaland African eats locally bred pig, but infected pork is liable to be eaten by him through ignorance, since the same system of meat inspection which exists in more advanced communities is not available to the local African who is therefore more liable to cysticercosis infection than is the European. The author has not seen a case in a white resident of Rhodesia.

The principal clinical feature of cerebral cysticercosis is recurrent epilepsy, with a varying number of seizures. The disease may often terminate in *status epilepticus*. Other mental conditions are described, but the author has not noted them in Africans.

Diagnosis is not easy, and depends on the demonstration of cysts which may not always be detectable by X-ray as calcification does not necessarily occur. Careful palpation may reveal the presence of cysts in the muscles, especially in the arms, shoulder regions and chest wall. They are about the size of a pea, oval or elongated and vary greatly in number.

In the brain, the cysts vary in size from a few millimetres to $\frac{1}{2}$ in to $\frac{3}{4}$ in. There may be only one cyst or very many and this variability in size, number and distribution is very great. When the cyst dies, toxic substances are formed which cause necrosis in the surrounding tissues. Later the necrotic tissue becomes fibrosed into a capsule having an inner layer of connective tissue and an outer cellular layer.

DEFICIENCY DISEASES

WATERLOW J. C. Fatty Liver Disease in Infants in the British West Indies. *Medical Research Council. Special Report Series No. 263* 84 pp., 5 text figs. & 26 figs. on 12 pls. [14 refs.] 1948. London H.M. Stationery Office [L.]

Among infants in the British West Indies a syndrome has been observed of which the main features are oedema, muscular wasting and fatty infiltration of the liver. The condition is clearly related to the disease reported from several parts of Africa and known as kwashiorkor or infantile pellagra, but differs from it in that such manifestations of vitamin B complex deficiency as buccal ulceration, fissuring of mucocutaneous junctions and depigmentation of skin and hair which are regarded as characteristic of kwashiorkor are often absent and never severe in the West Indian cases. Fatty change in the liver is regarded as the fundamental lesion and appears in West Indian babies in a relatively pure form, whereas in Africa it appears as part of a multiple deficiency state in which the clinical picture is complicated by the presence of various avitaminoses.

In accordance with this view evidence of liver damage was used as the criterion for selecting the 15 cases described in this report.

In the majority of cases the condition appeared soon after weaning at which time the diet consisted mainly of carbohydrate and contained very little milk. That inadequacy of diet at this period of life is widespread in the West Indies is also shown by weight curves the growth rate falls off markedly during the six months after weaning.

The presenting complaints were oedema and vomiting. There was gross muscular wasting, but subcutaneous fat was not completely lost. In consequence of this and of the presence of oedema the degree of weight loss was less than in many cases of simple starvation. The liver was enlarged, and hepatic failure appeared to be the primary cause of death in four of the five fatal cases.

Further investigation revealed a moderate to severe anaemia which was hypochromic and either normocytic or slightly macrocytic in type. Serum protein concentration was low (less than 4.5 gm per 100 ml. in 8 cases) the reduction being mainly in the albumin fraction. The serum phosphate values were similar to those found in control cases of simple undernutrition; there was slight hyperbilirubinaemia. The only test of liver function which proved of value was the bromsulphthalein clearance test and this showed impairment in all cases. The fat content of the stools was increased; the proportion of pig fat was normal.

Post-mortem examination in four fatal cases showed gross fatty infiltration of the liver, the fat in the liver was neutral fat, the phospholipid content was low. The only other abnormal findings were atrophy of voluntary muscle fibres, atrophy of the acinar cells in the pancreas and a moderate and variable amount of iron pigmentation in the liver.

Fatty infiltration was also demonstrated in surviving cases by means of liver biopsy, and repetitions of this procedure, with serial measurements of serum protein and bromsulphthalein clearance, were used to assess the response to treatment.

Administration of methionine, choline and inositol, in the doses used, appeared to be without effect, on the other hand, improvement occurred on a high intake of milk.

In addition to the 15 cases upon whom detailed investigations were carried out, 600 unselected babies of between six months and two years were examined clinically, and enlargement of the liver without oedema was found in over 10 per cent of them. In two of these cases of symptomless hepatic enlargement, further investigation showed normal serum protein concentration and normal, or almost normal, bromsulphthalein clearance, but liver biopsy revealed the presence of fat. It is concluded that such cases of simple hepatic enlargement represent an early stage of fatty liver disease, and this figure gives some idea of the probable prevalence of this condition.

Cirrhosis of the liver is not uncommon in children in that part of the West Indies where fatty liver disease is commonest. Material obtained by biopsy and at post-mortem upon cases of fatty liver disease provides some evidence that cirrhosis develops as a result of preceding fatty infiltration, and represents the final stage of the disease in those affected who neither die nor recover completely.

As regards the aetiology of the condition, the dietary histories, the absence of evidence of any infection or intoxication and the exogenous source of the liver fat led to the conclusion that fatty liver disease is due to malnutrition. The rarity and inconstancy of associated manifestations of vitamin deficiency suggest that the condition is not due to a specific avitaminosis, and therapeutic tests have shown that it is not due to deficiency of such factors as choline and methionine, which are lipotropic because they act as sources of labile methyl groups. It is, however, clearly associated with a low protein intake and a relative overloading with carbohydrate. Yet the picture is entirely different from that of simple starvation in which the protein intake is often equally low, in that in the latter condition there is loss of all body fat and no fatty infiltration of the liver. The factor determining which of the two clinical and pathological conditions is produced in protein deficiency and protein depletion appears to be the level of caloric intake, deposition of exogenous fat in the liver only occurring when there is a *relatively* high caloric intake.

Waterlow's work is of importance beyond the mere collection of new clinical, biochemical and pathological data about an interesting deficiency state. Although the exact cause of fatty liver disease in infants remains unknown, all that this investigation contributes tends to suggest that the ultimate solution of the problem will be found in an imbalance of nutrient intake, a distortion of metabolic pattern, rather than in any single specific deficiency. Advance has been made in defining the unsolved problems and in showing which of the results of experiments upon nutritional liver damage in animals, here discussed in detail, are or are not applicable to human pathology.

[The finding by Waterlow of a pancreatic lesion is of particular interest. Similar lesions have recently been described by other authors (see below) and the theory has been put forward that pancreatic damage is the fundamental lesion in the syndrome.]

There can be no doubt that fatty liver disease is widespread in the tropics and is an important contributor to the appallingly high infant mortality rate of many tropical territories. Indeed, recent work suggests that the condition is not confined to the tropics (VEGHELY *Lancet* 1948, Mar 27 497). There is here abundant evidence that a high carbohydrate, low protein diet given after weaning is an important, if not the only causative factor. The feeding of pap made from a variety of cereals, with an inadequate intake of milk or other good source of protein, is an exceedingly widespread practice throughout the world and a clear indication is given of the effect that correction of this dietary fault might be expected to have on infant health. Further evidence is produced that the development of cirrhosis of the liver in young people also a common and fatal disease in the tropics, may, in some cases, be traced to fatty liver disease in infancy [See also this *Bulletin* 1947 v 44 841 1948 v 45 635]

HOLMES, E. G. & TROWELL, H. C. Formation of Hepatic Glycogen in Normal Africans and in those suffering from Malignant Malnutrition. *Lancet*. 1948, Mar 13, 395-8 2 figs.

The formation of hepatic glycogen was studied in human subjects by estimations on samples of liver obtained by biopsy. As the authors point out, although it has been shown in experiments on animals that liver glycogen increases after glucose is given, this has never yet been directly demonstrated in man. For this reason alone the results are of great interest.

The subjects fasted overnight. In the morning, an initial sample of blood was taken for blood-sugar and serum-protein estimations and the initial biopsy was made. 50 gm. of glucose were then given intravenously and blood samples were taken after one hour and two hours. Biopsies of the liver were made in earlier tests after two hours, in later tests at both one and two hours after glucose had been given. The tests were made on four control subjects, eight patients with malignant malnutrition, one recovered patient, and one with sub-acute hepatic necrosis. With one exception—a child of two years—all the patients with malignant malnutrition were adults. The clinical picture in these cases has already been described (this *Bulletin* 1946, v 43, 363).

In both controls and malnourished subjects, the initial levels of liver glycogen showed wide variation (from about 10 to about 40 mgm. per gm.). In all the controls, the glycogen increased after glucose was given—the increase was sometimes greater at one hour than at two hours. In the patients with malignant malnutrition, the liver glycogen either fell or remained unchanged. In the one case of subacute hepatic necrosis, the initial level was low but was more than doubled two hours after glucose was taken.

The blood sugar in the controls had fallen almost to the initial level two hours after the test dose of glucose. In the malnourished subjects, on the other hand, it remained high. There was therefore a diminished glucose tolerance. Oral glucose tolerance tests in cases of malignant malnutrition showed a similar delayed fall in blood sugar.

The conclusion is drawn that in the patients with malnutrition the liver was unable to synthesize glycogen from glucose at the normal rate. It must, however, have retained some power of forming glycogen from other sources, if not from glucose since it was by no means glycogen-free. Moreover the power to mobilize glycogen could not have been entirely lost, since with one exception hypoglycaemia was not found even after 24 hours fasting. (It is of interest to compare these findings with those of BOSS see *Bulletin* 1947 v 44, 406) who found impaired glucose tolerance and low resting blood-sugar values in both acute and chronic starvation. See also DAVIS, this *Bulletin* 1948, v 45 633.

J. C. H. Atkinson

GILLMAN, J., GILBERT, Christine & GILLMAN, T. The Bantu Salivary Glands in Chronic Malnutrition with a brief consideration of the Parenchyma-Interstitial Tissue Relationship. *South African J Med Sci* 1947, Sept, v 12, No 3, 99-109, 8 figs on 2 pls [27 refs]

The Gillmans and their colleagues in Johannesburg, in their work over a number of years on the pathological histology of malnutrition in Africans, have not confined themselves to descriptive observations, although the facts so gained are of the first importance. They have in addition persistently tried to visualize the reactions of the body as a whole in a particular setting over a period of time—an approach that is both fruitful and stimulating.

The present paper is an example of this. The salivary glands have been little studied by morbid anatomists, because they are regarded as unimportant appendages. In fact, however, they can give useful information, for, as the authors point out, "the modifications in the structure of the salivary glands in human malnutrition represent only a facet of the more general alterations in metabolism, in which many other organs and tissues are implicated."

It is impossible to summarize briefly the details of the histological findings, for these, the original paper must be consulted. The main changes found in cases of malnutrition were —

i Atrophy of the glandular tissue. The acini were reduced in size, or had disappeared completely. Sometimes the cells reverted to a cubical shape, indistinguishable from that of the epithelium lining the small ducts. The serous cells were more susceptible to atrophic changes than the mucous cells.

ii Cystic dilatation of the ducts

iii Patchy accumulation of lymphocytes, particularly near the excretory ducts

iv Low-grade fibrosis, mainly round the ducts

v Cytosiderosis, seldom as severe as in the liver

When atrophy of acini, dilatation of ducts, and fibrosis occurred together, the end-result closely resembled the picture of cystic fibrosis in the pancreas.

In the parotid the changes were rather different. Enlargement of the parotid has frequently been noted in malnourished Africans. This seems to be caused mainly by an increase in size of the individual gland cells, there may also be an interstitial accumulation of fat. Parotid changes of this kind were found almost exclusively in males. Mixed parotid tumour is commoner in Africans than in Europeans, but other neoplasms of the gland are rare.

In the submaxillary and sublingual glands, the range of reactivity was similar to that of the liver, since it included atrophy, fibrosis, and cytosiderosis. Fatty change, however, was less common than in the liver, and less severe. The fact that fibrosis could occur without being preceded or accompanied by fat supports the view previously expressed by GILLMAN and GILLMAN [this *Bulletin*, 1948, v 45, 632] that there is no causal relation between fibrosis and fatty change. Similarly, atrophy and fibrosis occurred quite independently. It is therefore suggested that "an overgrowth of connective tissue, whether it occurs in the liver, pancreas, or salivary glands, does not pre-suppose any observable injury to the parenchyma although such injury may indeed be manifest at the chemical level. However, as in the liver, so in the salivary glands, one form of connective tissue overgrowth seems to be related to factors controlling the distribution of lymphocytes, since fibrosis is commonly associated with lymphocytic infiltration. It is suggested that there may be a general stimulation of the reticulo-endothelial system in response to large molecules, which are either produced endogenously, or absorbed from the gut as a result of defective pancreatic secretion. [For comment, see below] J C Waterlow

MAGALHÃES CARVALHO SCHMIDT M. M. & PEDRO A. G. Síndrome coelia-
distrofia plasmacarential hidropigénica. [Coeliac Syndrome following Ki-
Nutritional Deficiency with Oedema.] *J. Pediatr.* Rio de Janeiro 1
July 1948 No 7 141-51 3 figs. & 2 graphs. [22 refs.]

In previous papers [this *Bulletin* 1948 v 45 635] Dr Magalhães Car-
valho and his colleagues in Rio de Janeiro have described infants and children with
oedema, fatty liver and signs of multiple nutritional deficiency. The condition
is considered to be identical with kwashiorkor in Africa. They have
observed that many cases convalescing from this disease develop, after a
few weeks, the clinical picture of the coeliac syndrome. The abdomen becomes
protuberant and the stools pale, bulky and offensive. In spite of a voracious
appetite the child remains thin and may show residual signs of avitaminosis.

Twenty-four hour specimens of faeces were collected from three such children
on a mixed diet, which provided about 24 gm. of fat a day. Three other children
were put for three days on a diet of bananas and butter which was calculated
to provide 50 gm. of fat daily. Faeces were collected on the third day. Analysis
showed that in both groups the faecal fat content was within normal limits, and
the proportion of unsplit fat was normal, except in one case. The faeces in
these experiments were not collected quantitatively, however in other similar
cases the total weight of faeces excreted each day was measured and found to be
many times greater than normal. It is therefore argued that steatorrhea did
in fact exist although it is not apparent from the figures for faecal fat content.
The fact that there was no increase in unsplit fat is attributed to the fat-splitting
action of bacteria in the period between collection and drying of the faeces.

The functional capacity of the pancreas was investigated in six cases by
measuring the enzyme content of juice aspirated from the duodenum. The
child was given no food overnight and a tube was passed into the duodenum.
10 ml. of 33 per cent magnesium sulphate were given through the tube to
stimulate bile flow and a sample of bile was collected. Ten ml. of warm milk
were then given. 20-40 minutes later a sample of juice was aspirated, and after
a further period of 20-40 minutes a second sample. The trypsin and lipase
contents of the samples were measured. Estimations of amylase were abandoned
as unreliable. The measurements were made by standard methods and are
not described in detail. In all the cases both the trypsin and the lipase content
of the duodenal juice were below the lower limit of normal. For trypsin this
limit is given as 10 units while the range in the cases investigated was from
2 to 8 units. For lipase the range was from 2 to 30 units, compared with a
normal lower limit of 50 units. No measurements were made on control
cases.

In discussing their findings, the authors suggest that there may be a connexion
between pancreatic damage and fatty liver. This leaves open the question of
whether there is a definite causal relationship between functional impairment
of the pancreas and the clinical manifestation of the coeliac syndrome.

[Although it is necessary, a *CILMA* editorial point out, to avoid the narrow
perspectives often resulting from too great a concentration on one gland,
such as the liver, yet it is inevitable that in the study of any disease attention
should be directed now to one aspect now to another. In the case of kwashiorkor
or the focal point of interest at the moment, the pancreas, see this *Bulletin*
1948 v 45 635. In discussing their observation on the salivary glands the
Johannesburg workers have emphasized their causal significance. Examples
of the reactions of glandular tissue to malnutrition and as clues to the nature of
the relationship between parenchyma and interstitial tissue. But they also
have an obvious focal significance because of the close morphological and
functional similarity between salivary gland and pancreas.]

The findings of Magalhães Carvalho and his colleagues support the thesis that pancreatic damage is an important feature of kwashiorkor. The interpretation of the Brazilian results taken by themselves, would be difficult, since they were obtained during convalescence, and control subjects were not studied. However, they are in agreement with the work of VÉGHÉLYI in Budapest, who found decreased secretion of pancreatic enzymes in babies not getting milk. This preceded the development of oedema and enlargement of the liver. These observations have not yet been published in detail.

There has been little experimental work on the reaction of the pancreas to dietary deficiencies. FRIEDMANN and FRIEDMANN produced atrophic changes in the acinar cells of the pancreas, together with fatty liver, in rats given a low protein, high fat diet. KRISTAL (*S African J Med Sci*, 1947, v 12, 47) studied the pancreatic changes in rats fed on maize-meal porridge and fermented milk. These rats developed numerous lesions of the liver [see GILLMAN *et al*, *Bulletin of Hygiene*, 1945, v 20, 627]. Histological changes were found in the pancreas in 18 out of 30 rats. These changes included loss of granules, atrophy of acinar cells, cystic dilatation of ducts, fatty infiltration, and occasionally fibrosis.]

J C Waterlow

CHAUDHURI, R N & CHAKRAVARTI, H. **An Outbreak of Pellagra Syndrome in a Rural Area of Bengal** *Indian Med Gaz* 1947, Nov, v 82, No 11, 657-60

An outbreak of disease attributable to multiple deficiency of B-complex factors, in which a pellagroid dermatosis predominated, occurred in one section only of an Indian village. Exact dietary data are not reported, but it is evident that the diet of the whole village was deficient in protein and B vitamins. The only detectable difference between the diet of the affected families and that of those who showed no clinical manifestations was that the rice (which is the staple) of the affected group had many grains which were black in colour and bitter to the taste, whereas that of the affected families had none. The black rice all came from one small area, where the affected families had their paddy fields and where there was scarcity of water.

It was at first considered that the "black" degenerate grains might have lost most of their content of B vitamins, but their nicotinic acid content proved, upon analysis, to be within normal limits. It is possible that these "black" grains contained a toxic substance which precipitated the occurrence of the deficiency state.

BORKOW, A, FOWDEN, L, STEDMAN, M M, WATERLOW, J C & WEBB, R A. **A Growth-retarding Factor in Maize Bran** *Lancet* 1948, May 15, 752-3, 1 fig

An outstanding feature of endemic pellagra is its frequent association with the consumption of maize as a staple cereal. ALKROYD and SWAMINATHAN showed [this *Bulletin*, 1940, v 37, 797, *Bull Office Internat d Hyg Publique* 1941, v 33, 507] that this cannot be explained on the basis of nicotinic acid deficiency alone. In the search for a toxic or pellagrigenic factor in maize it has been shown that this cereal if fed in sufficient quantities, exercises a growth-retarding influence in rats (WOOLLEY *J Biol Chem*, 1946, v 163, 773, KREHL, HENDERSON, DE LA MUERGA and ELYENJEM, *ibid*, v 166, 531), the latter workers attributing the effect to amino-acid imbalance, especially in respect of tryptophan.

In 1947 two of the present authors investigated an apparent increase in pellagra in Basutoland and found evidence that this increase was related to an increase in the consumption of maize bran resulting from changes in milling practice.

Feeding tests have now been made upon weanling mice by means of firstly a diet containing 10 per cent. bran, secondly a diet comprising mostly bran-free maize flour and a standard diet. The diets contained 10 per cent. protein and were designed to avoid, as far as possible any amino-acid imbalance tryptophane being available in equal amounts in the test and control diets.

The animals fed upon the 10 per cent. bran diet showed a highly significant growth retardation when compared with control litter mates. No such growth-retardation occurred in the animals fed upon the maize flour diet nor in a series fed upon the 10 per cent. bran diet to which 5 mgm. nicotinamide per 100 gm. had been added.

This evidence most strongly suggests that the toxic factor in maize whose effect for rats and mice is growth retarding resides in the bran fraction and that the bran-effect is preventable by nicotinic acid. Extraction of the toxin has not yet been achieved.

As the authors emphasize retardation of growth in mice has no necessary reference to human pellagra. It is, however of the greatest importance to determine whether the factor in maize bran which has been shown to be growth-retarding for mice is toxic to man and whether it has any relation to pellagra. The results of work on these lines, which is now going on, may prove an important step in elucidating the aetiology of endemic pellagra.

FRANKLAND A. W. Deficiency Scrotal Dermatitis in P.O.W.s in the Far East.
B. U. Med. J. 1948, May 29 1023-R. (19 refs.)

Scrotal dermatitis associated with dietary deficiency was extremely prevalent among allied prisoners of war in the Far East. The present description is based upon 351 cases observed on Singapore Island.

Four forms, or degrees of the condition were recognizable clinically: (i) Mild acute dry in which there was redness and irritation of the scrotum under treatment or sometimes spontaneously a fine desquamation left apparently normal skin. (ii) Severe chronic dry bright red erythema extending to thighs, penis, perineum and anal region. (iii) Chronic wet weeping dermatitis of scrotum and thighs which without treatment often developed into (iv) ulcerated and oedematous with great swelling heavy secondary infection sometimes with *C. d. phloeris* progressing in the worst cases to pyaemia, gangrene which with marked generalized toxic symptoms, sometimes terminated fatally.

The incidence of the condition was highest when the riboflavin content of the diet was low conversely when the latter could be kept at an adequate level cases did not occur. Associated deficiency diseases both in individuals and in general incidence were those usually attributed to hyporiboflavinosis namely glossitis, cheilosis, angular stomatitis and corneal degeneration.

Some success was achieved by various forms of local treatment but this was often incomplete and the relapse rate high. On the other hand, Marmel appeared to have a specific curative effect in uncomplicated cases and greatly hastened recovery in those cases for whose secondary infection local treatment was necessary.

The aetiology of the condition is discussed and it is concluded, on a considerable weight of evidence that this form of scrotal dermatitis is due to deficiency of riboflavin or of some factor closely allied to it. Dr. Frankland

CHEN TZU-TA Angular Blepharitis in Ariboflavinosis—a not well known
Clinical Manifestation of Riboflavin Deficiency *Chinese Med J* 1948,
Jan, v 66, No 1, 1-4

"Three cases of angular blepharitis occurring as a manifestation of ariboflavinosis are described. A survey in a prison in Nanking was made. Twenty-three out of the 97 prisoners examined were found to have ariboflavinosis and 4 out of these 23 had angular blepharitis. This sign has not yet received much attention as a clinical manifestation of ariboflavinosis."

DERMATOLOGY AND FUNGUS DISEASES

SALVIN, S B Complement Fixation Studies in Experimental Histoplasmosis
Proc Soc Exper Biol & Med 1947, Nov, v 66, No 2, 342-5, 2 figs
[11 refs]

In some recent work on the complement-fixation test for the diagnosis of histoplasmosis, by TENENBERG, HOWELL, FURCOLOW & BUNNELL [this *Bulletin*, 1948, v 45, 644], and by CROSS & HOWELL [this *Bulletin*, 1948, v 45, 643] the antigens used were histoplasmin (a filtered autolysate of the mycelial growth of *Histoplasma capsulatum*) and the polysaccharide extracted from histoplasmin. SALVIN, on the other hand, used, as antigen, the intact, formalin-fixed, yeast-like form of the fungus, designated "YP", which was cultivated on a special medium devised by him [*Bulletin of Hygiene*, 1948, v 23, 360].

Rabbits inoculated intravenously with living cultures of *Histoplasma capsulatum* in the yeast form, yielded an antiserum which reached its highest titre (about 1:512) in 30 days. Six different strains of *H. capsulatum* were used and the sera of 15 immunized animals were tested for complement-fixation with the YP and crude histoplasmin antigens. All of the sera reacted strongly with the YP antigen, the highest titre being 1:512, but only 8 reacted with the histoplasmin antigen, the highest titre not exceeding 1:128.

On the matter of the specificity of the complement-fixation test for histoplasmosis, the YP antigen gave no reaction whatever with 10 human sera from cases of coccidioidomycosis, 8 anti-*Coccidioides* rabbit sera, 8 anti-*Blastomyces* rabbit sera and 4 anti-*Candida* rabbit sera, but the histoplasmin antigen gave a reaction, albeit in low titre, with some of the sera in each of these groups. The specificity of the complement-fixation reaction with the YP antigen was also demonstrated in a test with 30 human sera from healthy persons and 2 sera from cases of histoplasmosis.

HEAT STROKE AND ALLIED CONDITIONS

NELSON, N, EICHNA, L W, HORVATH, S M, SHELLEY, W B & HATCH, T F
Thermal Exchanges of Man at High Temperatures *Amer J Physiol*
1947, Dec 1, v 151, No 2, 626-52, 15 figs

In the study of physiological responses to high environmental temperatures, there is a great need for relationships to be established whereby the thermal stress imposed by the environment can be described in terms of the various factors which together make up that environment. The present paper describes a calorimetric study of the thermal exchanges between man and his environment. The total heat exchange was broken down into its several components, and physical constants were determined. The observations were made on

healthy young men exposed to dry bulb temperatures ranging from 80 to 120°F with wet bulb temperatures of 70 to 91 and wind speeds of 30 to 600 feet per minute. Experiments were done with the subjects standing nude or clothed, and walking while clothed. The walking tests were done on a treadmill at a speed of three miles per hour with a three per cent. gradient. The metabolic rates while walking were about 160 Cal. per sq. m. per hour. The temperature and humidity of the air, the speed of air movement, and the radiation from the walls were measured during each test period. Measurements on the subjects included rectal temperatures, skin temperatures at various points, surface temperatures of clothing, oxygen consumption, heart rate, evaporated sweat loss and total sweat loss. From the temperatures of the skin and of the surface of clothing, weighted mean skin and surface temperatures were calculated.

In nude subjects, the maximum coefficient of evaporation varied as the 0.4 power of the air velocity. It is remarked that in evaluating the influence of wind speed and vapour pressure on the rate of evaporation the study must be confined to conditions where the skin or clothing surface is completely wet. With low rates of sweating the rate of evaporation is not influenced by wind speed. Sweating rates high enough to measure the maximum coefficients of surface evaporation in clothed men were probably not reached, but charts are given which show the coefficients actually found.

The coefficients of convection vary as the square root of the air velocity. The convection coefficients for clothed subjects were 23 to 44 per cent. higher than those for nude subjects. This is in agreement with the estimated differences between the surface areas of clothed and nude men.

The radiation coefficients of nude subjects agreed with the theoretical value based on emissivities of wall and skin of 1 and a radiation area of 91 per cent. of the geometric area of the body. For some unaccountable reason the coefficients of radiation for clothed subjects were much lower than would be predicted from reasonable assumptions as to the surface area and emissivity of the clothing.

Movement of the arms and legs while walking resulted in an increase in the apparent wind speed. When the men were walking at three miles per hour this apparent increase was 150 feet per minute above the wind speed in the tunnel.

T. Bell, J.

NELSON, A. A. SHELLEY, W. B. HORVATH, S. M. EICHNA, L. W. & HATCH, T. F. The Influence of Clothing, Work, and Air Movement on the Thermal Exchanges of Acclimatized Men in various Hot Environments. *J. Clin. Investigation*. 1943, Mar. & 27, 239-16, 4 figs.

Partitional-calorimetric studies were made of four well-acclimatized young male subjects. They were acclimatized by walking for four hours a day while dressed in trail uniforms, in an environment with a dry bulb temperature of 120°F and a wet bulb of 85°F. The calorimetric tests were carried out in a wind tunnel placed inside the laboratory hot room. The men stood or walked on a treadmill. The walking was at a speed of 3 miles per hour with a grade of three per cent. Walking caused an average energy expenditure of 160 Cal. per sq. m. per hour and standing caused one of 135 Cal. per sq. m. per hour. Seven temperature levels were studied. In these the dry bulb temperature ranged from 80 to 120°F and the wet bulb from 70 to 95°F. At each temperature level wind velocities of 30, 50, 150, 300 and 600 ft. per minute were employed. At each condition three men were studied standing nude, standing, hilled and walking clothed. The men spent 7½ hours in the heat each day except Sunday.

Increasing the wind speed from 30 to 600 feet per minute did not cause a striking change in the rectal temperature—in no case was the average rectal

temperature changed 1°F . Such an increase in air movement generally caused significant reductions in the skin temperatures of the subjects. The surface temperatures of clothed men followed the same pattern as skin temperature until the air temperature exceeded 96°F . With air temperatures higher than body temperature, the surface temperature of the clothed body rose with increasing air movement and occasionally reached 105°F . When the air temperature was 120° , the total sweat loss of clothed subjects was strikingly reduced by increase in air movement. With wet bulb temperatures of 88° or 91°F , increase in air velocity caused appreciable reductions in pulse rates.

The body heat production for a given amount of work remained unchanged irrespective of change in environmental conditions. When at high temperatures resting men wore clothing they gained less heat by convection and radiation than when they were nude, and therefore their evaporative heat losses were smaller.

ADOLPH, E F **Tolerance to Heat and Dehydration in Several Species of Mammals** *Amer J Physiol* 1947, Dec 1, v 151, No 2, 564-75, 11 figs [27 refs]

Comparisons of tolerance to heat and dehydration were made between several species of mammals. The species considered were dogs, cats, rabbits, guinea pigs, rats, and mice. These vary greatly in their capacities of evaporation, cooling, and in the tissue temperatures that they can endure. Together with body size, these appear to be the principal factors which determine tolerance to heat. A consistent sign of lethal conditions was found to be a rectal temperature of between 41.7° and 43.4°C , the critical value varying with the species. It appeared that heat stroke resulted from hyperthermic injury to regulatory tissues which were not identified. In some instances when animals had been subjected to gradual increase of rectal temperature and then cooled, death was delayed for periods up to 26 hours.

Dehydration through panting was copious in cats and dogs, but was limited in the other species. A considerable degree of dehydration did not bring about any change in the rate of evaporation loss. Dehydration rendered the animal very sensitive to warm atmospheres, presumably owing to the limitation of the circulation brought about by a depleted plasma volume. Failure of the circulation to transport heat to the surface caused an explosive rise of rectal temperature. In hot atmospheres animals that were allowed water to drink at will did not drink enough to maintain their body weights, and, except in the case of dogs with only small water deficits, when deprived of water they subsequently drank less than enough to recover their body weights.

GROCOTT, J F L **Comfort Cooling in the Tropics** *J Inst Heating & Ventilating Engineers* 1948, Apr, v 16, No 153, 36-64, 9 figs [28 refs] Discussion 64-79

In planning an installation for cooling buildings in the tropics one should be able to ascertain the following meteorological data —

- (a) maximum temperature for each month and season,
- (b) average maximum for each month,
- (c) average summer maximum,
- (d) the number of days on which the average summer maximum is exceeded in steps of 3°F , e.g., if average maximum is 110°F how often is 112° exceeded and how often 115° and so on.

Design recommendations are made on the basis of the experience of the Anglo-Iranian Oil Company during the past 20 years. When the external

healthy young men exposed to dry bulb temperatures ranging from 80° to 120° F with wet bulb temperatures of 70° to 91° and wind speeds of 30 to 600 feet per minute. Experiments were done with the subjects standing nude or clothed, and walking while clothed. The walking tests were done on a treadmill at a speed of three miles per hour with a three per cent gradient. The metabolic rates while walking were about 160 Cal. per sq. m. per hour. The temperature and humidity of the air, the speed of air movement, and the radiation from the walls were measured during each test period. Measurements on the subjects included rectal temperatures, skin temperatures at various points, surface temperatures of clothing, oxygen consumption, heart rate, evaporated sweat loss and total sweat loss. From the temperatures of the skin and of the surface of clothing, weighted mean skin and surface temperatures were calculated.

In nude subjects, the maximum coefficient of evaporation varied as the 0.4 power of the air velocity. It is remarked that in evaluating the influence of wind speed and vapour pressure on the rate of evaporation the study must be confined to conditions where the skin or clothing surface is completely wet. With low rates of sweating the rate of evaporation is not influenced by wind speed. Sweating rates high enough to measure the maximum coefficients of surface evaporation in clothed men were probably not reached, but charts are given which show the coefficients actually found.

The coefficients of convection vary as the square root of the air velocity. The convection coefficients for clothed subjects were 23 to 24 per cent higher than those for nude subjects. This is in agreement with the estimated differences between the surface areas of clothed and nude men.

The radiation coefficients of nude subjects agreed with the theoretical value based on emissivities of wall and skin of 1 and a radiation area of 91 per cent of the geometric area of the body. For some unaccountable reason the coefficients of radiation for clothed subjects were much lower than would be predicted from reasonable assumptions as to the surface area and emissivity of the clothing.

Movement of the arms and legs while walking resulted in an increase in the apparent wind speed. When the men were walking at three miles per hour this apparent increase was 150 feet per minute above the wind speed in the tunnel.

NELSON, N. A., SKELLEY, W. D., HORVATH, S. M., EICHMA, L. W. & HATCH, T. F. The Influence of Clothing, Work, and Air Movement on the Thermal Exchanges of Acclimatized Men in various Hot Environments. *J. Clin. Investigation*, 1948, Mar. v. 27, No. 209-16, 4 figs.

Partitional-calorimetric studies were made of four well-acclimatized young male subjects. They were acclimatized by walking for four hours a day while dressed in twill uniforms in an environment with a dry bulb temperature of 120° F and a wet bulb of 88° F. The calorimetric tests were carried out in a wind tunnel placed inside the laboratory hot room. The men stood or walked on a treadmill. The walking was at a speed of 3 miles per hour with a grade of three per cent. Walking caused an average energy expenditure of 160 Cal. per sq. m. per hour and standing caused one of 53 Cal. per sq. m. per hour. Seven temperature levels were studied. In these the dry bulb temperature ranged from 80° to 120° F and the wet bulb from 70° to 88° F. At each temperature level wind velocities of 30, 50, 150, 300 and 600 ft. per minute were employed. At each condition three men were studied standing nude, standing, clothed and walking clothed. The men spent 7½ hours in the heat each day, except on day

Increasing the wind speed from 30 to 600 feet per minute did not produce a striking change in the rectal temperature—in no case was the average rectal

temperature changed 1°F . Such an increase in air movement generally caused significant reductions in the skin temperatures of the subjects. The surface temperatures of clothed men followed the same pattern as skin temperature until the air temperature exceeded 96°F . With air temperatures higher than body temperature, the surface temperature of the clothed body rose with increasing air movement and occasionally reached 105°F . When the air temperature was 120° , the total sweat loss of clothed subjects was strikingly reduced by increase in air movement. With wet bulb temperatures of 88° or 91°F , increase in air velocity caused appreciable reductions in pulse rates.

The body heat production for a given amount of work remained unchanged irrespective of change in environmental conditions. When at high temperatures resting men wore clothing they gained less heat by convection and radiation than when they were nude, and therefore their evaporative heat losses were smaller.

GROCOTT, J F L **Comfort Cooling in the Tropics** *J Inst Heating & Ventilating Engineers* 1948, Apr, v 16, No 153, 36-64, 9 figs [28 refs] Discussion 64-79

In planning an installation for cooling buildings in the tropics one should be able to ascertain the following meteorological data —

- (a) maximum temperature for each month and season,
- (b) average maximum for each month,
- (c) average summer maximum,
- (d) the number of days on which the average summer maximum is exceeded in steps of 3°F , e.g., if average maximum is 110°F how often is 112° exceeded and how often 115° and so on.

Design recommendations are made on the basis of the experience of the Anglo-Iranian Oil Company during the past 20 years. When the external

temperature ranges from 90°F to 125°F the internal temperature should be 75 to 83. This range has been used as the basis for all buildings except the general hospital. In the hospital, a uniform condition of 75°F with 50 per cent. relative humidity is required in summer while in winter the requirement is 70°F with 30 to 50 per cent. relative humidity. In operating theatres a temperature of 70°F with 50 per cent. relative humidity is demanded all the year round although the external temperature ranges from 40°F to 120°F. The changes between external and internal conditions are sometimes very great. Experience has revealed no ill effects of these contrasts, while great benefits have accrued to the patients.

There are notes on the relation of building construction to air cooling. Modern buildings are constructed on the conventional lines of similar buildings in temperate zones. The roofs are mostly flat or of slight pitch, and constructed of tile on insulation. Full advantage is taken of verandas, canopies, Venetian slats, etc. to exclude sunlight and most buildings are finished in light colour. There is also a detailed discussion of the appropriate methods of cooling various types of buildings.

BERTOLO A. & LUGO G. Contributo isto-patologico allo studio della gangrena (rimo-oro-faringite mutilante dei tropici). [Histological Study of a Case of Gangrene; *Acta Med. Italica*. 1948 I b v. 3, No. 2, 32-8, 10 figs. (13 refs. English summary)]

The authors relate the case of an Arab woman 52 years of age who had first shown signs about 20 years ago of a small painless nodule affecting the left nostril, rapidly breaking down and spreading till much of the nose, mouth and face was destroyed by a typical gangrene. A series of photographs depicts graphically the terrible state of this unfortunate woman. Search for *Mycobacterium* and for *Mycobacterium tuberculosis* was repeatedly negative also for *T. spumosa*, *Portia leishmanii*, rhinoscleroma and blastomycetes. The W.R. had once been reported positive in 1929 but was negative in each of the next three years; the Kahn and Meinicke tests were always negative. All sorts of treatment were tried—arsenicals, mercury, bismuth, antimonials, sulphonamides, N-vitamins, etc. but all in vain and the patient died.

Histological examination of the various tissues and organs was made of different parts of the local lesions of the lung, heart, liver, spleen and kidneys. Photomicrographs indicate the condition found but there is nothing characteristic in them and none of the changes characteristic of leprosy, tuberculosis (including lupus), syphilis, or rhinoscleroma was to be made out and the authors see no reason for regarding gangrene as a complication or sequel of

yaws, they incline to the view that it is distinct from all of these, in short, that it is a condition *sui generis*, or in the medical jargon of to-day a "separate clinical entity"

ORTNER, E Ueber Lathyrismus
May 7, v 60, No 18, 291-3

[On Lathyrism] [11 refs]

The author states that in the concentration camp at Vapniarka, near Odessa, lathyrism was very rife. Of about 1,400 inmates, 800 or 57 per cent showed the disease in an early or late stage. In September 1942, 1,200 men came to the camp they had been in confinement for more than two years in different Rumanian prisons on "political or racial grounds". They were in a poorly nourished state and their food in the camp consisted of only 400 gm of cooked *Lathyrus sativus* and 200 gm of bread made of 80 per cent barley meal and 20 per cent chopped straw. Their chief complaints were of cramps, mostly in the calves, but also in the arm muscles, strangury and frequency of micturition, up to 20 times a day. Within two months walking became increasingly difficult, with spastic paresis. Ulcers would form on the toes, especially the big toe, and progress to gangrene, in many cases symmetrical and ending fatally. Three cases are described in detail.

ENTOMOLOGY AND INSECTICIDES GENERAL

ANDUZE P J Fauna hematófaga del Distrito Maturín (Est Monagas, Venezuela)
los Culicidos [The Mosquitoes of Maturín District, Monagas, Venezuela]
Rev Med Vet y Parasit Caracas 1947, Jan-Dec v 6, Nos 1/4, 121-6

STAGE, H H DDT to control Insects affecting Man and Animals in a Tropical Village J Econom Entom 1947, Dec, v 40, No 6, 759-62, 1 fig

During a period of five weeks in March and April 1946, all animals (except three calves) and all surfaces of buildings, inside and out, in Moengo, a village in Surinam, South America were treated with either 2.5 per cent DDT suspension in water or with 5 per cent DDT oil solution. The author describes the formulations, spraying equipment and the methods of trapping and then notes the effectiveness against certain insects. After two weeks, mosquitoes were difficult to find in cowbarns, but they began to be caught again after ten weeks. The numbers in light traps in the centre of the village fell from 900 and 400 to 13 and 3 respectively, a few days after treatment, 'later there were even fewer. At breeding places where there were no buildings or animals within half a mile, the number of mosquitoes increased by 200 to 300 per cent after ten weeks. In a house treated with the DDT suspension, mosquitoes were released two to three months after treatment and all were dead in three to four hours after eleven months, 2,000 others were released and all were dead in eight hours, after fifteen months, 2,000 were released and 60 per cent were dead after seven hours. In a similar house treated with the DDT oil solution, 2,000 mosquitoes were released after eleven months some were still alive after 24 hours, but 50 hours later only two could be found alive. The species used in these tests are not named, but a complete analysis is to be published elsewhere. A list of species found in the locality is given.

Horn flies, bed-bugs, fowl ticks (*Argas persicus*) and chigoes (*Tunga penetrans*) are thought to have been eradicated. The number of cockroaches (? *Periplaneta americana*) is said to have been reduced by 90 per cent and there was a

reduction in the number of cattle ticks (*Boophilus annulatus macropus*). The programme for dealing with dog fleas broke down, and dogs are still infested.

LABORATORY PROCEDURES

BLACK, R. H. Leishman's Stain adapted for Use with Histological Sections.
Ann Trop Med. & Parasit. 1948, Apr. v 42, No. 1 5-3 3 figs. in 1 pl.

This method is recommended as an alternative to Giemsa's stain for sections, particularly to demonstrate the erythrocytic and exoerythrocytic forms of *Plasmodium gallinaceum*. Thin sections are treated for 5-10 minutes with a saturated aqueous solution of picric acid. They are then washed in water and stained for 25 minutes with a mixture consisting of one part of Leishman's stain with two parts of distilled water. This should be freshly prepared. The section is then immersed in running water for about 10-15 minutes, dehydrated in xylol-acetone mixtures and mounted in a neutral mounting medium. Van Gieson's strain was originally employed, but tests showed that it was the picric acid constituent which was responsible for the good results. This substance appears to act by virtue of its acidity. Its pH was 12, and when decinormal hydrochloric acid was substituted for picric acid essentially similar results were obtained. The tissue cells stain brilliantly and in some organs, differentially. In the kidney, for instance, the collecting tubules are stained magenta, while other tubules give a different reaction. Malaria parasites in red blood cells are easily recognized, and exo-erythrocytic forms are very deeply stained.

The author admits that the method is not an improvement on Giemsa's stain and the absence of differential staining of the chromatin and the cytoplasm of parasites will detract from its value in parasitology.

REPORTS, SURVEYS AND MISCELLANEOUS PAPERS

NEDERL. TIJDSCHR. V. GENESK. 1948 May 22, v 92 (ii) No. 2 1566-80
 2 graphs. Nederlandse Vereniging voor tropische geneeskunde.
 Vergadering op zondag, 23 September 1947 te Utrecht (HUTTENLOFF A. A.
 President). [Netherlands Association for Tropical Medicine.]

Four subjects were dealt with at this meeting held at Utrecht in September 1947: plague, tetanus, the beriberi heart and malaria.

Two methods of campaign against plague have prevailed in Java: the housing of the indigenous population, with protection against rat intrusion and prophylaxis by means of living plague vaccine. The vaccination languished under Japanese occupation and the occurrence of abscesses after inoculation raised the suspicion that these were mitigated plague lesions. These were however only manifestations of contamination by pyogenic organisms and the plague bacillus in question was proved to be still just a virulent. In the restoration of the vaccine of Otten the Harlan strain has now been left out and only the original Tjwidedj strain used. The latter strain immunised the guinea-pigs in minimal doses but not the house rat. It is the guinea-pig, which came closest to man in its immunological response and the Tjwidedj strain is therefore to be preferred for routine use. Protection is reduced for three months unaltered and to a less degree for an entire year.

A close argument on the characteristics of the beriberi electrocardiogram was presented by AALSMEER mainly to show how this differed in oriental regions from that of America and the west. The conclusion seems to be reached that the western beriberi heart is not of the same type as the oriental *shoshin* and that recognition of an alcohol-beriberi heart must be given consideration.

Malaria is treated under the heading of "Colonization Kesir," which signified really the establishment by the Japanese of a concentration camp in a region full of all the possibilities of intense malaria infection. The vector mosquito was *A. aconitus*. Very careful work was done both in the way of records and of quinine prophylaxis. The records, which would have given valuable information on the incidence of relapses and fresh infections, were lost. A most fortunate circumstance in this camp was that quinine was available in abundance which, with the energetic measures adopted to deal with the mosquito menace, served to bring malaria under medical control. This régime followed on the first explosive outbreak of malaria. Orderlies were appointed who made daily visits to their sector of the camp. Slight cases of sickness were reported and examined the same day. If the patient had fever, a thick drop preparation was made of his blood and if it was positive he received a first treatment of 30 tablets of bisulphate of quinine—6 each day, of 220 mgm each. After a week's interval he received the same 5-day course again. A table showing the frequency distribution of attacks in 295 cases is given, where the greatest number, 130, suffered only one attack and the numbers fell steadily to 3 cases with 9 attacks each.

W F Harvey

POPPER, L. *Medizinisches aus Bolivien* [*Medical Notes from Bolivia*] *Wien Klin Woch* 1948, May 14, v 60, No 19, 297-301

An interesting though short account of the diseases met with in Bolivia prefaced by some facts on the physical geography of the country. There are [or were, at the time of writing] 500 doctors practising there, most of them in the towns. *Tuberculosis* has been recorded as common among the soldiers, and the author's predecessors have stated that 7 per cent of the regiment of 400 die of it. The author, therefore, undertook an investigation, examining all recruits. An intracutaneous test showed 38 per cent reacting positively. Further observation of the members of one unit discovered no cases in the next three months. Later, some, especially those who had not reacted to tuberculin, developed an exudative pleurisy and a few of them actual pulmonary tuberculosis. By careful attention the fatality rate fell from 7 to 1 per cent. Another unit not so controlled and watched over, and housed in unfavourable conditions, had a 10 per cent mortality in six months. Symptoms, in the earlier stages at least, are very slight. In the following year 3,540 men were kept under observation and among them were 65 cases of pulmonary tuberculosis, 58 of exudative pleurisy, and 19 of other forms, 142 in all, or 4.0 per cent morbidity [not 152 and 4.3, as stated]. *Dysentery* also is fairly rife, some amoebic but more commonly bacillary—the water, from ponds and wells, is often contaminated. *Leishmaniasis* is not seen in Chaco, but occurs in north-east Bolivia. Other ulcerous conditions met with are phagedaena (associated with spirochaetes and fusiform bacilli and occasionally diphtheroids) and blastomycosis, but this last is uncommon. The author has seen one case of coccidioidomycosis. *Malaria* is, of course, present, mostly benign tertian the relative frequencies of benign tertian, subtertian and quartan are said to be 30:3:1. Chronic malaria is often afebrile, but the parasite can nearly always be found, it was missed in only 4 per cent of 600 cases. No case of blackwater fever was seen by the author. Nutrition is poor and consequently resistance to disease is low. The average diet for an adult is only 1,600-1,800 calories

and that mainly made up of carbohydrate. In the Bolivian highlands, the amounts consumed per head per year are 21 kgm. meat 36 litres of milk and 0.22 kgm. of fat— the lowest in the world. In the lower levels where cattle are reared, the quantities of meat and milk are greater but the calorie value is lower. The soldier's ration is about 3 000 calories but the constituents are badly balanced.

Hookworm infestation is widespread and severe anaemia is far from uncommon both *Ancylostoma* and *Necator* are the cause. About 70 per cent of recruits were passing hookworm ova, 20 per cent. *Ancyra* 15 per cent *Trichuris* and 6 per cent. *Strongyloides stercoralis* ova. *Balanitidum* also is common. *Filaria*s especially *M. ozzardi* is often met with. Chagas disease is not very common in spite of the fact reported by many that *Triatoma infestans* and *Paratrypanosoma megastus* were seen and the author found more than half of them infected. Leprosy was occasionally seen. Yellow fever has been almost stamped out by the efforts of the Rockefeller Foundation. Eaters of Coca suffer from paresis and neuro-muscular atrophy especially of the peroneal area, and from hyperaesthesia and anaesthesia of the conjunctiva later those who indulge in this habit become wrecks and succumb readily to intercurrent disease. Venereal diseases are not rare. Lympho-adenitis inguinale is fairly common. Of the infective fevers *d. pluvialis* is rare scarlet fever practically unknown measles occurs inland and among adults whooping-cough in children is usually mild.

TROPICAL DISEASES BULLETIN

Vol 45]

1948

[No 9

SUMMARY OF RECENT ABSTRACTS*

VII HELMINTHIASIS

[Continued from p 669]

Nematodes

General—STOLL (p 667) must be read in the original, he has written a valuable study, under the title of *This Wormy World*, of the probable incidence of human helminthiasis

In his account of a helminthological survey of N Rhodesia, BUCKLEY (p 909) points out that as the Africans eat any part of the carcass of animals, the presence of eggs of certain worms in human stools does not prove true infection—the eggs themselves may have been ingested in the meat eaten *Necator americanus* was the only hookworm found in this survey, and the incidence of infection was higher in cassava plantations (usually situated near villages) than in millet plantations (further away and probably with more scattered faecal deposits) *Strongyloides fülleborni* and *S. stercoralis* were also found, but *Ascaris lumbricoides* was not widespread. The last is usually associated with a congested population. *Acanthocheilonema perstans* was found in about 6 per cent of blood specimens examined, but *Wuchereria bancrofti*, *Onchocerca volvulus* and *Loa loa* are not endemic

EINHORN and MILLER (p 215) have summed up their series of studies on intestinal helminthiasis in children of the Panama canal zones. They discuss age incidence, symptomatology and treatment

LOUGHLIN and STOLL (p 335) describe an acid-ether-xylol technique for examination of faeces for helminth eggs. Tests indicated that this gave better results than the Telemann and DCF techniques with *S. japonicum*, *Trichuris* and infertile *Ascaris* eggs. The test is described in detail

OLIVER-GONZÁLEZ (p 729) discusses the immunological relationships between polysaccharides derived from various infecting organisms, including several worms parasitic for man, and pneumococci. Cross-reactions, and the techniques used, are discussed in the original paper, which should be consulted

Hookworm Infestation etc—CANTACUZÈNE and LUPASCO (p 529) have found hookworm infection in coal miners in Rumania where in some mines the rate of infection reaches 96 per cent. The sanitary conditions in the mines are bad, the atmosphere is warm and damp and the miners usually work barefoot

*The information from which this series of summaries has been compiled is given in the abstracts which have appeared in the *Tropical Diseases Bulletin* 1947 v 44. References to the abstracts are given under the names of the authors quoted and the pages on which the abstracts are printed

Clinical signs include digestive troubles, nausea, vomiting, epigastric pain and occasionally diarrhoea. KAMALOV *et al* (p. 224) describe a focus of hookworm infection in Georgia, Russia.

STOLL *et al* (p. 444) show that the incidence of hookworm infection is much higher in United States troops from the southern coastal States than from other parts, the majority of the worms being *Necator*. In troops exposed to infection in the Philippines most of the worms were *Ancylostoma*. There was no correlation between egg count and haemoglobin percentage and very little between high egg count and high eosinophilia. There is good evidence that infection may be acquired by launderers who handle soiled garments which have been allowed to stand for several days in a damp condition. LONGHURST and STOLL (p. 735) take up this point. They have proved that active filariform hookworm larvae may be found in large numbers in blankets and nightclothes of patients with hookworm infection, if these are damped repeatedly and kept for several days. The larvae can migrate several inches. Launderers have been infected in this way in Guam and no doubt similar infection may be spread in hospital patients if the bed-clothes are dirty and damp.

KAMALOV (p. 668) has shown that infective hookworm larvae are capable of climbing vertically on blades of grass to a height of 22 cm, provided that there is a film of moisture on the grass. A person coming into contact with these larvae may be infected, even if wearing shoes and socks.

MOST *et al* (p. 443) found hookworm infection in 6.4 per cent. of American soldiers who had not been outside the United States and in 11.5 per cent. of soldiers who had served in the Pacific theatre. At an American Army General Hospital in the South Pacific, hookworm infection was found in 13 per cent. of those examined; other nematodes were also found.

BLACK (p. 336) discusses the co-existence of tuberculosis and hookworm infection in Florida, where the latter is prevalent. The association of hookworm infection and sputum positive for tubercle bacilli, or of hookworm anaemia with tuberculosis, indicates a relatively unfavorable prognosis. HERBERTS (p. 225) refers to the relationship between anaemia due to hookworm disease and lack of iron in the diet, and the disease known in West Africa as dibolia, which in some respects resembles kwashiorkor.

CHAUDHURI and MUMERJI (p. 820) report a case in which tetrachlorethylene appeared to be the immediate cause of death, but the patient was very emaciated as a result of gross malnutrition. It is probably wise to withhold even such safe drugs as tetrachlorethylene from patients in this condition.

WRIGHT and GOLD (p. 224) have found 26 cases of the Loeffler syndrome in 78 patients with creeping eruption thought to be due to *Ancylostoma braziliense*. They think that the pulmonary infiltration is an allergic reaction to antigens from the larvae in the skin. The systematic treatment of creeping eruption due to *Ancylostoma braziliense* with drugs is disappointing. HITCH (p. 941) found no definite evidence that certain antimonials and one arsenical had any lethal effect on the larvae though they did relieve some of the symptoms, probably through a larvostatic action. ASTERUP (p. 846) has observed human infection with *Uncaria stenophila*, a hookworm of certain carnivores. Larvae were detected in the many small skin pustules. The mode of infection was not clear though the author suspected a dog, which commonly slept with the patient.

HARTZ (p. 101) has given a detailed description of the pathological changes found in the intestinal wall in a case of strongyloidiasis with internal auto-infection. The post mortem examination was made 40 minutes after death, and the findings cannot therefore be attributed to post mortem change. Details cannot well be abstracted further and should be sought in the original.

GILLMAN (p. 1062) states that in Indo-China the type of *S. stercorarius* commonly found usually shows the indirect (sexual) cycle of development but

that the direct (asexual) cycle also occurs This is the reverse of the position in temperate climates, but the view (expressed by some workers) that the direct cycle does not occur in the tropics is wrong

WATSON (p 337) sums up the points of differentiation between hookworm, *Strongyloides* and *Trichostrongylus* infections
DE OLIVEIRA (p 96) prefers a preparation of carbon tetrachloride and oil of chenopodium for hookworm infection, and gentian violet for *Strongyloides*
of a Portuguese village (DE MEIRA and COITO p 1014) Hsu (p 1008) made a survey of intestinal parasites in school children and in university freshmen and servants, in Chengtu, where *A. lumbricoides* was common *Ascariasis* is also common in New Orleans, and SWARTZWELDER (p 225) shows that the chief symptom associated with it is abdominal discomfort, fever is quite often present Intestinal obstruction occurred in 18 of 202 cases BARBER (p 736) refers to the surgical aspects of *Ascaris* infection, quoting several cases from Cyrenaica

OLIVER-GONZÁLEZ (p 226) has investigated the functions of the non-immunizing antigens present in *Ascaris lumbricoides* The subject is complicated and is related to blood groups, the paper should be read in the original
MUKERJI and BHADURI (p 836) report quite favourably on certain indigenous drugs, derived from Indian plants, in the treatment of *Ascaris* infections
Filariasis—FLOCH (p 103) shows that in a group of people in French Guiana the incidence of *W. bancrofti* was of the order of 12-18 per cent of adults
Culex fatigans is apparently the sole vector He discusses the relationship between elephantiasis and filariasis, concluding that elephantiasis may arise as a result of chronic streptococcal infection, and doubting its aetiology connexion with filariasis FLOCH and DE LAJUDIE (p 922) found *W. bancrofti* in 12-13 per cent of Creoles in French Guiana

HERNÁNDEZ MORALES and GONZÁLEZ BARRIENTOS (p 228) found microfilariae of *W. bancrofti* in the night blood of 4.35 per cent of 1,256 prisoners in Porto Rico, and BERCOVITZ and SHWACHMAN (p 338) found them in the night blood of 3.42 per cent of young Porto Ricans, very few of whom gave clinical histories consistent with filarial disease

In part of Hyderabad the incidence of filarial disease was found by FAROOQ and QUTUBUDDIN (p 669) to be 0.2 to 4.9 per cent Microfilariae were found in only 1 of 138 persons with filarial disease, but in 15.5 per cent of 584 apparently normal persons Most of the microfilariae were *W. bancrofti* (92.4 per cent) *W. malayi* was found in 7.6 per cent *Culex fatigans* is the only proved vector, but species of *Mansonia* were present in the vicinity

Examination of two American soldiers with filariasis contracted in the South Pacific showed that the microfilariae of *W. bancrofti* were present in the peripheral blood in greater numbers during the day than during the night, though they were never absent EYLES *et al* (p 837) think that these microfilariae showed a degree of diurnal periodicity rather than, as is usually accepted, no periodicity Microfilariae of *W. bancrofti* found in the Central Philippines show modified periodicity (AVERY, p 445)

FOSHAY (p 837) describes the cuticular morphology of certain microfilariae
PRATT and NEWTON (p 104) have studied in detail the progress of embryos of a periodic strain of *W. bancrofti* in *Culex fatigans* In the conditions of these experiments the average numbers of larvae found per mosquito decreased from 48.7 at 16½ days after feeding, to 8.8 at 30½ days, the loss indicating the number that left the mosquitoes by the proboscis At 16½ days there is considerable migration from the thorax to the abdomen, and 2 days later the larvae leave the abdomen for the head and proboscis After 18½ days the larvae

begin to escape from the proboscis but this escape may be independent of feeding, for instance where the proboscis contains 5 larvae or more.

HENRIARD *et al.* (p. 103) show that *Anopheles f. vestitus* and *A. maculatus* are easily infected with *W. bancrofti* in the Belgian Congo. *Aedes aegypti* also supports its development but *Culex fatigans* is a poor vector in this area. PERRY (p. 391) has found filarial infection in up to 5% per cent. of *Anopheles farauti* in the New Hebrides and Solomon Islands. HARPER *et al.* (p. 953) state that in the Polynesian islands the vector of *W. bancrofti* is *Aedes pseudo-scutellaris* but that in the New Hebrides and Solomon *Anopheles farauti* and (probably) *A. kulcrossi* are chiefly responsible.

Studies on possible vectors of *W. bancrofti* indigenous to the United States are reported by NEWTON and PRATT (p. 337): three of the mosquitoes examined could be occasional vectors, and two others *Culex pipiens* and *Picoph. discolor* are definitely capable of transmitting the infection under suitable conditions. Development of *W. bancrofti* from the S. Pacific, to advanced or infective stage was found by EYLES and MARR (p. 838) in a number of mosquitoes indigenous to the United States, especially in *Culex pipiens* and *C. fatigans*, the latter being the commonest mosquito in the southern States.

GULLIARD (p. 1014) has succeeded for the first time in infecting both *Aedes aegypti* and *Aedes albopictus* with *W. bancrofti*. He discusses the apparent refractoriness of *Aedes aegypti* to *W. bancrofti* in some places, and its susceptibility in others: there seem to be races of the parasite which vary in adaptability to the vectors.

FRANKS (p. 107) shows that the incidence of microfilariae in the blood is relatively high in persons (on the island of Okinawa) whose blood is of group A.

HIGHBY (p. 446) has shown that the number of microfilariae found per unit volume of blood in the stomachs of mosquitoes is greater (by 7 to 13 times) than the number found in the same volume of blood of the patient on whom the mosquitoes have fed. This is then put forward as a method of concentration which may be useful in diagnosis.

In the course of a paper on intradermal tests for filaria is in which an antigen prepared from *D. filariae immutis* was used SALZGERS *et al.* (p. 109) make the point that *W. bancrofti* is endemic in the southern United States. With this test they obtained a considerable number of immediate or delayed positive reactions in men from the S. Pacific either with filariasis or who had been in the endemic areas but also in few not so exposed. It appears that infection with any filaria will give a positive reaction but probably not infection with other nematodes. The test is a useful diagnostic aid. WILKINSON (p. 838) has used an antigen from *D. filariae immutis* in a skin test for filariasis in British Guiana, and finds it positive in almost all infected persons. He does not think that the presence of intestinal worms give rise to false positive reactions, and he notes that patients with lephantiasts and without microfilariae in the blood gave strong reactions.

FRANK (p. 446) has demonstrated two antibodies in persons infected with *W. bancrofti*: one directed against the microfilariae and one against the adult worms. He discusses the possible use of antigen from adult or microfilariae for diagnostic tests.

WARREN (p. 943) has shown that the complement fixing group specific factor common to *D. immutis* and *W. bancrofti* is present in *L. arum* and *Trichinella spiralis* though not in filaria.

GILLIES *et al.* (p. 647) have examined the plasma antimony concentration and urinary antimony excretion in man during treatment with or without antimonial. The high plasma level of Venetianum suggests that this may be the drug of choice in the treatment of blood parasites. The latter is usually trivalent rather than pentavalent compound as suggested by CLARKSON *et al.*

(p 924) describe the tests which indicated that Neostibosan and Neostam gave distinct promise of usefulness in *W bancrofti* infections. With Neostibosan, microfilariae disappeared completely from 23 of 35 patients, and did not return even after a long period of observation. Its effect is to kill the adult worms. BROWN and THETFORD (p 338) report appreciable reduction in microfilariae of *W bancrofti* in some patients as a result of daily injections of anthiomaline, there was no obvious difference in the rate of excretion of antimony between those who did and those who did not respond well to the treatment. CULBERTSON and PEARCE (p 229) show that repeated administration of Stibanose (or Solustibosan) to cotton rats will eradicate infection with *Litomosoides carini*, and they urge its trial in man.

WELCH *et al* (p 1015) report on certain members of the group of cyanine dyes which have shown considerable promise in the treatment of *L carini* infections of cotton rats.

ORTO and MAREN (p 1083) have found that certain substituted phenyl arsenoxides are active against adult filariae of cotton rats and dogs, they are experimenting with these in man.

DUBOIS (p 229) reports two cases in which prurigo was associated with infection with *Loa loa*. JOHNSTONE (p 530) gives an account of his own infection with *Loa loa*, noting that the Calabar swellings were frequent in hot weather but rare in cold. Four adult worms were removed at different times from the eye, and after that the Calabar swellings have ceased to occur. No microfilariae were ever found in the blood.

GABATHULER and GABATHULER (p 924) found onchocercal nodules in a considerable proportion of people in a village in eastern Tanganyika, but in comment GARNHAM points out that they did not use the skin-snipping technique. Immature stages of Simuliidae were present in all the streams. BOZICEVICH *et al* (p 669) have used antigens from *Onchocerca volvulus* and other filarial worms, in the diagnosis of onchocerciasis by intradermal and complement fixation tests. The *O volvulus* antigen was more sensitive than any of the others and gave fewer false positive reactions in persons infected with other worms.

RUIZ REYES (p 1015) gives Anthiomaline as an auxiliary to surgical measures in the treatment of onchocerciasis.

In one of the three onchocerciasis areas of Kenya, where *Simulium neavei*, the vector, breeds in limited stretches of two rivers, GARNHAM and McMAHON (p 1084) have succeeded in eradicating the flies, probably permanently, by applying to the rivers emulsions of DDT in oil and water, to produce a DDT concentration of 2 ppm for 30 minutes at intervals of 10-14 days for 6-7 months. This was enough to kill the developing forms of the flies in successive batches, and at length no living flies could be found. Re-establishment of the flies is unlikely. No serious harm was done to other forms of life. The technique adopted is described.

PEEL and CHARDOME (p 339) have found *Microfilaria streptocerca* in chimpanzees in the Belgian Congo and after having examined the adult worms, have assigned them to the genus *Dipetalonema*.

In an enquiry into *Dracunculus medinensis* infection in a village in the Deccan India LINDBERG (p 925) shows that step wells are apparently more dangerous than curb wells, though the latter are also associated with many infections. Infection was rare under the age of 4, but rose to 85 per cent at age 30-35, after which it fell. Most infected persons had only one or two worms but one had 50. In most cases the head of the worm appeared below the knee. The chief intermediate host was *Thermocyclops vernalis*. The same author (p 925) shows that incidence is high in Jodhpur where the inhabitants depend on rain water collecting in shallow depressions. The period of onset

is highest between May and September—high temperature is an important factor for the development of larvae in the intermediate host.

SHARMA and HUSAIN (p. 737) report on infection of dogs, in India, with *Dracunculus medinensis*.

WHARTON (p. 106) has successfully transplanted adult *Lisomosoides carinii* from infected to uninfected cotton rats. SCOTT (p. 447) describes the infection of cotton rats with the filaria *Lisomosoides carinii* by the bite of *Lapomysus bacoti*. He (p. 839) describes a technique for quantitative infection of the cotton rats with larvae removed from the mites by teasing, and injected into the cotton rats by syringe. With his colleagues (p. 840) he describes the technique of rearing the mites.

Enterobius infection.—SWELLENGREBEL and SCHLITZNER (p. 448) have proved that eggs of *Enterobius vermicularis* at least 3 days old, can infect and that if in any patient further infection can be prevented, the worms cease to be passed out after a relatively short time and the infection dies out. The difficulty in practice is that infection from fingers and from materials is so difficult to prevent. The authors discuss treatment.

BIJLMER (p. 111) reports a case in which very large numbers of immature *E. vermicularis* were found in the tissues of the rectal wall of a man who died from gangrenous ulceration of the small and large intestine. The worm invasion was probably a secondary phenomenon.

GELLER (p. 927) has examined *E. vermicularis* (and the comparable *P. salinus ambigua* of the rabbit) obtained from various parts of the large intestine in relation to the stage of development of the eggs they contain. He concludes that these worms cannot multiply in the intestine without being discharged. MADSEN (p. 110-840) thinks that the migration of female *Enterobius vermicularis* out of the anus is determined by the maturation of the eggs in the uterus, and that the worms wander out to lay eggs in batches, periodically, at intervals of about one month.

Trichuris and Trichinella spiralis.—Experiment in a mental hospital indicated that the treatment of choice for *Trichuris* infections was administration of emetine in enteric-sealed tablets by the mouth. BIRNBOIM *et al.* (p. 928) obtained the best result with 2 grains for 8 days.

WIRD (p. 111) describes an outbreak of trichuriasis in Sweden in which 35 of the 37 infected persons were positive to precipitin test. The incubation period was 14-24 days, shorter in severe cases. The onset was often acute with oedema of the eyelids, nausea, vomiting, diarrhoea, fever, headache and eosinophilia. Skin tests with *Trichinella* antigen were not reliable. ROTTE (p. 117) describes 5 immunological tests used in this outbreak, of which the most sensitive is the micro-copie precipitin test in which 1 mm. larvae are placed in suspected serum, forming a precipitate if the serum has immune bodies. OPPENHEIM *et al.* (p. 449) describe an outbreak of trichuriasis in prisoners of war acquired from uncouked pork; the chief symptoms were weakness, fever, headache, muscle pains, swelling of the eyelids, swelling, nasal tenderness and anorexia. Treatment was symptomatic since the authors do not believe that any anthelmintic will affect adult worms. *Trichinella* could not be found in faeces, gastric contents, spinal fluid or blood. An outbreak of trichuriasis in New York City is described by SCHLESINGER *et al.* (p. 113); this was due to uncouked pork sausages. The incubation period was from 1 to 35 days. There were no deaths and the authors comment on the relatively low fatality rates in recent years compared with those which occurred in the 19th century. The explanation probably lies in the fact that as a result of improved control measures, the infections have recently been much lighter than before. Symptoms are described, and the point is made that almost all patients had eosinophilia of over 10 per cent. The eosinophil count is the most useful single laboratory test

for trichiniasis—better than precipitin and intradermal tests (which are discussed), and considerably better than biopsy

LEHMENSICK (p 230) has found *Trichinella* in foxes in Germany and suggests that one cycle of human infection may be fox-wild-rat-house-rat-pig-man

PORTWOOD and SANDERS (p 448) have studied the electrophoretic and allergenic properties of fractions of larvae of *Trichinella spiralis*, but the details of this work should be sought in the original

Charles Wilcocks

RABIES

SORIANO LLERAS, A Nota sobre la rabia en Colombia [Note on Rabies in Colombia] *Repertorio Med y Cirugia* Bogota 1948, Mar, v 3, No 9, 677-8

In the present article—the continuation of a previous paper on the same subject [this *Bulletin*, 1947, v 44, 1029]—the author deals with the occurrence of human rabies in Colombia and with the effect of specific treatment thereon

Unfortunately certain of the statistics are inaccurately presented and greatly lessen the value of an otherwise informative contribution The following, for example, are difficult of reconciliation

- (a) of the 125 deaths from human rabies during the six years 1940-45, there were 54 (43·2 per cent) among bitten persons, who had received complete courses of treatment with SEIPLE'S carbolized fixed virus vaccine and 71 (56·8 per cent) among those who had had no treatment or but few injections,
- (b) the numbers of deaths from human rabies in the period 1940-45 were, beginning with 1940 25, 26, 29, 17, 20 and 12, i.e. a total of 129,
- (c) of the 38,625 bitten persons treated between 1940 and 1945 there succumbed to rabies 129 or 0·34 per cent

On the other hand it seems clear that of 3,023 bitten persons, who during the four years period 1942-45 had received full treatment, only 38 or 1·26 per cent developed rabies This result is held to establish the protective value of the vaccine in use on the ground that according to the estimate of the Pasteur Institute, Paris, 16 per cent of persons bitten by rabid animals and remaining without vaccine treatment fall victim to rabies

It is noteworthy that in Colombia the shortest incubation period of rabies observed in man was 6 days, the longest 5 months [In nature it is seldom under 10 days]

The annual number of cases of human rabies in Colombia shows that the problem is much more serious there than in many other American countries, in the neighbouring countries of Ecuador and Venezuela, for instance, human cases are rare [In the United States cases of human rabies totalled 143 in 1890 averaged 63 annually between 1910 and 1920, numbered 105 in 1928 and thereafter declined In Canada human cases are rare]

LILOU, Y C & KOLO C C Premier cas chinois de maladie d'Aujeszky [First Case of Aujeszky's Disease in China] *Ann Inst Pasteur* 1948, Feb v 74, No 2, 130-33

In this paper the authors describe the first occurrence in China of the condition known as Aujeszky's disease (pseudo-rabies 'mad itch')

The following paragraphs summarize the clinical manifestations in the affected animal—a cat belonging to a Shanghai family—and the laboratory findings on which diagnosis was finally based

Clinical history—The disease commenced suddenly and ran its fatal course in early January 1947. Between the 5th and 7th the cat had recurrent attacks of vomiting and diarrhoea. On the 7th, profuse salivation and anxious expression were noted. On the 8th there was paresis of the hind legs. On the night of the 8th-9th, the cat died. The clinical diagnosis made by an experienced veterinarian was rabies. On this diagnosis two persons bitten while handling the animal, sought anti-rabies treatment.

Laboratory Investigations—(a) Histopathological examination.—On section, Ammon's horn showed neurophagy, perivascular infiltration with leucocytes, eosinophilic cell inclusions resembling Negri bodies in size and shape, smaller red-staining bodies situated extracellularly and within capillaries.

(b) Inoculation experiments.—Material from the medulla introduced into rabbits produced intense itching as principal symptom and death in short space of time after the intracerebral inoculation death occurred in from 24 to 60 hours and after scarification on the shaven skin, in 5 days. Moreover in the rabbit inoculated by the skin route a spinal ganglion showed, on section, the cytological changes described by Hirst as characteristic in Ajazsky's disease: disappearance of the basal substance, eosinophilic staining of the protoplasm, invasion of the nucleus by acidophilic granules and alteration in or loss of the nucleolus.

The authors consider the death of the cat to have been due to Ajazsky's disease and base their diagnosis on the following points:

(a) Although the cat during its illness did not appear to have suffered from "mad itch" nevertheless rabbits inoculated with its medulla showed intense pruritus as a prominent symptom.

(b) Although on section of the cat's brain, cell inclusions resembling Negri bodies were found in Ammon's horn such finding is not frequent in the brains of normal cats.

(c) Neurophagy and perivascular infiltration are more marked in Ajazsky's disease than in rabies.

(d) The incubation period in intracerebrally inoculated rabbits was of very short duration (1-3 days).

(e) The histopathological examination of a spinal ganglion removed from a rabbit which had been inoculated by the scarification method and had died in 5 days revealed a cytology described by Hirst (this Bulletin 1934: 31-146) as characteristic of AJAZSKY'S disease.

[The diagnosis is further supported by clinical signs in the affected cat: abrupt onset and rapid development of illness; profuse salivation and short paralytic stage soon before death.]

RELIOVA, R. V. The Efficacy of our Local Anti-Rabies Vaccine. *J. Philippine Med.* 4: 1948, Mar. 4: No. 3: 129-33. 1 graph.

The anti-rabies vaccine prepared by the Department of Health Laboratories at Manila consist of a 1 per cent suspension of fixed mouse brain and spinal cord in distilled water containing 0.5 per cent phenol. Such prepared suspension is kept in the refrigerator for 5 or 6 months before use.

In the paper under review the author presents experimental proof of the vaccine's efficacy—its antigenicity as determined by the Hirst mouse test, being invariably in excess of the National Institute of Health minimum requirement for anti-rabies vaccines on sale is 1,000 MLD protection.

MALARIA

MONACI, V. L'esacerbazione dell'endemia malarica e l'anofelismo nel territorio di Venezia [Increase of Malaria Endemicity and of Anopheline Prevalence in the Neighbourhood of Venice] *Riv di Malarologia* 1947, Aug., v. 26, No. 4, 191-211, 1 map & 1 chart. English summary (9 lines)

After an epidemic of malaria in 1929 in which 10,084 cases were reported in the Venice Province the incidence of the disease declined rapidly. The annual number of cases reported in that province in each of the four years 1937-1940 approximated 2,400. Thereafter there was a greatly increased prevalence, 4,730 cases in 1941, 9,286, 12,105, 13,772 and 11,233 in the succeeding years to 1945. From July 1943 to August 1944, the author carried out an anopheline survey of the area. Catching stations were established, both dwelling houses and stables, at distances of one kilometre along the courses of the Rivers Livenza-morta, Sile, Lemene, Piave nuovo and Gorgonze and the Canale di valle. Estimations of the saline content of waters were also made. *A. sacharovi* and three races of *A. maculipennis* were found, *messeae*, *maculipennis* and *melanoon*. *A. sacharovi* was found where endemic malaria was most severe.

Norman White

DE NEGRI, U. Sorgenti metanifere e malaria nel Polesine (Nota preventiva) [Marsh Gas Borings and Malaria in Polesine] *Riv di Malarologia* 1946, Dec., v. 25, No. 6, 217-23, 1 fig. & 1 map.

In 1934 the sinking of a bore in the Donada Commune of the Province of Venice, with the object of finding a supply of drinking water, failed in its purpose but disclosed the presence of marsh gas, methane, at a depth of 124 metres, and of still greater quantities at 265 metres. Subsequent exploration revealed the abundance of this source of methane and the possibility of utilizing the gas for industrial purposes. The abundance of the gas, the growing demands of industry and the scarcity of fuel occasioned by the war resulted in large-scale developments. At the present time there are more than 60 centres of exploitation each of them containing a number of bores, up to 20 to 25 in some cases. Their depth varies from 200 to 300 metres. More than half the total of more than three hundred bore-holes are situated in the Po Delta.

With the gas is a gush of a large quantity of water having a saline content of from 14 to 24 per cent. NaCl. This has resulted in raising the saline content of near-by collections of water making them more favourable for the breeding of *A. sacharovi*, the most formidable vector of malaria in this part of Italy. Thus arose an important factor determining the markedly increased prevalence of malaria that characterized the war years. Other operative factors were the dispersal of population caused by the dangers of bombing, the artificial flooding of certain areas for purposes of defence, neglect of maintenance of canals, reduced antimalaria staff, scarcity of larvicides, and reduced resistance of the population occasioned by malnutrition, etc.

The elimination of the malaria hazard caused by methane bores should not be difficult. The salt water could be drained through pipes to discharge in water courses of sufficient volume to reduce the salinity to an insignificant level.

Norman White

to 60 in Cokloco and in Haute Mana et Haut Approuague respectively. Parasite rates run more or less parallel from 5 per cent. in St. Laurent-du Maroni, 6 in Cayenne to 48 per cent. in Cokloco.

P. falciparum is everywhere more prevalent than *P. vivax*. This is interesting in view of the fact that in 1917 Marcel Leger reported that 68 per cent. of all infections were due to *P. vivax* and only 28 per cent. to *P. falciparum*. Over a period of 8 recent years positive blood examinations have revealed the presence of *P. falciparum* in 81 per cent., *P. vivax* in 17 per cent. and *P. malariae* in 1.5 per cent.

Gametocyte indices, Ross's endemic indices and splenometric indices are calculated for each region. They all show that Cokloco, Corossou and Haute Mana and Haut Approuague are highly malarious; most of the coastal communities are also very malarious, Itacoubo Regina, Sinnamary, Koumou, St.-Georges Ouanary and Mana. Endemicity is very low in Cayenne, Saint Laurent and in the Souvenir area. Malaria is likewise but little prevalent among the Galibi Indians of the villages of Conachi and Itacoubo.

The annual epidemic of malaria in French Guiana occurs in the dry season. Twenty-one species of *Anopheles* have been identified in French Guiana. *A. darlingi* constituted 91 per cent. of the total captured in houses. Its season of greatest prevalence, June to August, is the epidemic malaria season. *A. gyesalis* accounted for 48 per cent. of the captures outside human dwellings.

Norma White

CATILLO R. Répartition du paludisme en Equateur [Distribution of Malaria in Ecuador] *Bull. Soc. Path. Exot.* 1948, v 41, Nos. 1-2, 28-31.

The author gives a general account of the malaria problems of Ecuador.

The country is divided into three clearly defined zones. Along the west coast is a region of low-lying plains. The most important anopheline is *An. melanocephalus* and the population is highly infected with malaria. Transmission occurs in the six rainy months, and particularly at the end of this period when rivers dry up and leave chains of pools. The second zone lies between the two main chains of the Andes. The altitude is above 3,000 ft. and it is said that mosquitoes occur up to 8,000 ft. but the upper limit of native malaria is not stated. In this zone the principal vector is *Anopheles pseudopunctipennis* *s. adensis*. It occurs in hot alleys, presumably at a considerable altitude. In a part of this zone the valley of Chillos the insect has been completely eradicated (method not stated). The malaria in this zone in the Andes is clinically significant.

The third zone lies to the east of the mountains in the upper part of the Amazon basin. There are very large marshes and to the east one descends into a moist equatorial climate. Important vectors are *Anopheles (Kertessia) darlingi* and *An. albimanus* in water holding plants (Bromeliads). In the marshes *A. darlingi* is the prevalent vector.

All parts of the country are malarious and the disease is a major problem in many areas.

CRADET A. Aspectes del problema malarico mundial, medios para su solución en la Costa del Perú. Aspects of World Malaria. Means of dealing with the Malaria Problem in the Coast of Peru. Publicaciones de la Dirección General de Salud Pública. Departamento de Malaria. 1947. 41 p. 11.5 x 7.5 p.

ALLEN E. I. Food and Malaria. *Amer. J. Trop. Med.* 1948 May 24, 3: 349-56. 2 parts.

A general discussion.

Twenty-six patients were treated with chloroquine—nine had acute relapses within 3 months. One relapsed 7 months and one 9 months after treatment. Eleven other patients complained of slight symptoms suggestive of relapse but self-medication was responsible for negative blood findings. The total failure rate was 84 per cent—similar to the rate following mepacrine treatment.

Of 63 patients treated with quinine-pamaquin who were followed from 6 to 1 months none showed a laboratory relapse but 16 stated that they had had symptoms suggestive of an attack of malaria. No laboratory relapses occurred among 40 other patients followed for less than 6 months.

The authors found that in the treatment of acute malaria relapses and for suppressive therapy, chloroquine was as effective as mepacrine—moreover it was better tolerated and does not have the yellow-dye discoloration effect of mepacrine. It is, however, no more effective than mepacrine in preventing relapses. Quinine and pamaquin combined, under controlled observation and restricted activity of the patient, afford a safe and effective means of reducing the relapse rate.

ADRIKARI V. H. Suppressive Mepacrine Treatment to the Staff of B.A. Railway in 1945. *Indian J. Malariology* 1947 June v 1 No. 357-45 2 graphs.

During the malaria transmission season of 1945 and for one month after an attempt was made to give one tablet of mepacrine a day to each employee of the Bengal Asam Railway. This demanded an organization of considerable magnitude for the staff numbered some 48,000 in 135 stations. In areas where *A. stephensi* was the carrier the administration extended from April to November inclusive. In *A. fluviatilis* areas the drug was given from June to January. The results appear to have been highly satisfactory. There was a very considerable reduction in malaria incidence and general sickness rates as compared with previous years. Not a single case of blackwater fever was encountered in previous years several cases occurred. No death from cerebral malaria was recorded.

MAIER J. Quinacrine Levels in Plasma of Persons with Infectious Jaundice during and after Suppressive Malaria Therapy. *Am. J. Trop. Med.* 1948, May 28, No. 3 365-6.

The plasma level of quinacrine during its administration for the suppression of malaria, and the rate of disappearance of the drug from the plasma after the treatment was stopped, were normal in patients with infectious hepatitis.

LAMINI S. C. Paludrine in Malaria—Clinical Observations. *J. India Med. Ass.* 1947 Nov. v 17 No. 2, 27-32.

The author reports on the treatment with paludrine of 36 patients suffering from acute malaria. There were 31 *P. vivax* and 5 *P. falciparum* infections. The results were comparable to those obtained with adequate doses of mepacrine. No toxic effects were noted. One-day single-dose method of treatment is not considered satisfactory. The dosage found satisfactory by the author was 0.2 gm. twice daily for 4 or 5 days and then one similar or smaller dose daily until a total of 3 gm. had been taken.

VISWANATHAN D. K. & BAILY J. D. Experiments with Paludrine in the Chemotherapy of Malaria. *Indian J. Malariology* 1947 June 1 No. 2, 307-28.

These observations were carried out in the Bombay Presidency. In Ahmedabad, Valsar and Belgaum the study was confined to the jail populations.

In the two former places malaria is moderately endemic, the transmission season extending from September to January, Belgaum has little indigenous malaria. Some observations were also carried out in a few villages in the Kanara District where malaria is hyperendemic. The results are recorded in great detail. It was found that paludrine in weekly doses of 100 mgm for adults, 50 mgm for children aged 5 to 12 and 25 mgm for children aged 2 to 4 gave satisfactory results as a clinical prophylactic. These doses were not absolutely effective however, and their administration twice weekly is recommended. A single dose of 300 mgm effects clinical cure in all three forms of infection. Gametocyte production continues after clinical relief and the disappearance of asexual parasites from the peripheral blood after 8 weekly doses of 100 mgm the gametocytes show degenerative morphological changes. In rural areas, clinical prophylaxis with weekly doses is not practicable, but for the treatment of clinical attacks in such areas paludrine, 300 mgm in single doses, is most valuable (smaller doses for children). Tablets might safely be left in the hands of lay village officers for distribution. *Norman White*

MULLICK, K B & GUPTA J C Intravenous Paludrine in Malaria *Indian Med Gaz* 1947, Nov, v 82, No 11, 666-8

The authors report the use of intravenous injections of a solution of paludrine in the treatment of malaria. The solution was made in bulk. 50 gm were dissolved in 2,500 cc of normal saline. The solution was left in a tall jar for 24 hours. The clear supernatant fluid was siphoned off and autoclaved for 30 minutes under 20 lb pressure. 15 cc were injected intravenously.

There were no immediate reactions in any of the 50 patients so treated. In only five cases was a second injection called for. This was given on the following day. Four patients complained of anorexia and 3 of insomnia but it was not possible to determine whether paludrine was responsible for these symptoms. *Norman White*

CHOU, T Q, FU, F Y & KAO, Y S Antimalarial Constituents of Chinese Drug, Ch'ang Shan, *Dichroa febrifuga* Lour *J Amer Chem Soc* 1948 May, v 70 No 5, 1765-7

"From the Chinese drug Ch'ang Shan identified as *Dichroa febrifuga* Lour, there have been isolated umbelliferon, 4-quinazolone, a base with the composition $C_{18}H_{23}O_3N_3$ and a water soluble alkaloid named dichroine. The last compound has the composition $C_{16}H_{21}O_3N_3$ and undergoes easily isomeric change with the formation of three isomerides which are provisionally named α - β - and γ -dichroines, being convertible into each other under suitable conditions. Regarding their antimalarial activity, the γ -isomeride shows the greatest, and the α -isomeride the least. Based on the results of oxidation and alkaline hydrolysis dichroine appears to be composed of 4-quinazolone and a pyrole derivative which requires further investigation. Dichroine forms both normal and acid salts and a nitroso compound. The isolation of 4-quinazolone from a natural plant, Ch ang Shan, affords a remarkable coincidence with the chemical research for antimalarials along this line." [See also this *Bulletin*, 1948, v 45, 578]

CASTANA, V & MILANI-COMPARETTI, P Studi sulla splenoriduzione nella malaria con sympatol e adrenalina [Reduction of Splenomegaly of Malaria with Sympatol and Adrenaline] *Riv di Malarologia* 1947, June, v 26, No 3 137-52 [16 refs] English summary (5 lines)

The authors report on the treatment of 72 patients suffering from malaria by a modified Ascoli method. sympatol was used in place of adrenaline. The

Intravenous injections were associated with the administration of the usual antimalarial drugs. Sympatol was shown to be preferable to adrenaline in all respects. It was easier to administer the immediate symptoms following injection pallor tachycardia, the feeling of constriction in the chest headache etc. were much less marked and more transient with sympatol the contraction of the spleen was more prolonged the number of injections necessary is much less than the thirty daily injections of adrenaline in graduated doses, advocated by Ascoli. In most cases, 6 or 7 intravenous injections of sympatol were sufficient to obtain comparable results. Only in exceptional cases, in which the reduction of splenomegaly was delayed or incomplete were 8, 10 or 12 injections required.

HENRY A. F. V. *Prémunothérapie catalytique du paludisme subaigu et du paludisme chronique. Parasitologie partielle et hémochromatophénol* [Catalytic Premunotherapy of Subacute and of Chronic Malaria.] *Revue de Malariologie* 1947 June v. 24, No. 3 115-30. (Refs. in footnotes.)

Sufferers from subacute or chronic malaria and patients who, through stress of circumstances, have lost their state of premunition to malaria derive the utmost benefit from undergoing a cure in certain hydromineral establishments such as that of Encausse les Thermes (Haute Garonne) if that cure be reinforced by appropriate chemical treatment. The state of premunition may be very rapidly regained. The treatment appears to exercise a catalytic action on all the bodily forces, various glands and the reticulo-endothelial system. In an endeavour to find other means of modifying the interaction of host and parasite the author turned his attention to autohaemotherapy. He has evolved a method of treatment for which he claims great success.

The chronic malaria patient is given preliminary treatment—a daily injection of from 0.8 to 1.0 gm. of quinine for 3 days, and 3 tablets of premaline on each of the two succeeding days. Two days after this treatment some 50 to 70 cc. of blood are withdrawn. The blood is added to distilled water 10 cc. like 1 to 50 cc. distilled water. (The blood should give a clearly positive melanoflocculation test and contain no parasite in thick smears.) The blood in distilled water is left at room temperature for 7 or 8 hours and then placed in a refrigerator till the following day. It is then centrifuged, the clear red fluid decanted and placed in graduated bottles. Carbolic thionine is then added, 0.5 cc. to 40 cc. of haemolysed blood solution (thionine 1 gm. carbolic acid 8 gm. water 100 gm.) After mixing well it is left for 4 hours. Saline solution, 15 per 1,000 is then added in amount equal to one-quarter of the volume of the haemochromatic fluid. Carbolic acid 5 per cent is added to the saline solution before mixing, the amount being one-tenth of the combined volume of saline and haemochromatic solutions. A final centrifugation completes the preparation, to which the name haemochromatophénol is given.

Haemochromatophénol is administered subcutaneously the dose for an adult is 30 cc. An injection is given on each of three successive days, the first being given 36 hours after the withdrawal of blood. Three or four days after the third injection, a fourth and last injection is given. In most cases one series of injections is sufficient. In cases with very large splenomegaly a second series may be necessary when the whole process is repeated.

Spectacular results have been obtained—a veritable catalysis of or aneasology. The author discusses at considerable length the possible contribution of each of the various elements of the treatment to the success achieved.

HEILBRON I The Role of Chemistry in combating Tropical Diseases *Nature*
1948, June 19 956-60

A review of modern work on chemotherapy and insect control in malaria and trypanosomiasis

COVELL, G Bats, Clover, Water Lettuce and Malaria *Indian J Malariology*
1947, June, v 1, No 2, 243-51 [27 refs]

This paper deals with three theories concerned with the prevention of malaria that have received wide publicity from time to time in the lay press None of them has stood the test of serious investigation

Bats as potential destroyers of mosquitoes on a large scale came into prominence in 1909 as a result of the advocacy of Dr Campbell of Texas Attempts to turn his observations and claims to practical account have invariably failed, but his ideas have had recent adherents

The suggestion that clover might have antimalarial properties originated from d'Herelle He thus explained the absence of malaria from areas in which clover is abundant He suggested that coumarin ingested by the female mosquito from clover might inhibit the development of the malaria parasite Investigation has shown that clover has no effect on the incidence of malaria, but d'Herelle's theory has recently received influential advocacy

The water lettuce (*Pistia stratiotes*) according to Dr Roy of Murshidabad, Bengal, was always present in local water collections in his district wherever malaria was prevalent and absent from all healthy areas The removal of the weed from highly malarious villages had completely eradicated malaria Investigation has conclusively shown that Dr Roy's theory is untenable

The lesson to be learned from all this is epitomized in the dictum of Darwin which heads this paper "The most hazardous of human tendencies is the drawing of general conclusions from limited experience" *Norman White*

INDIAN J MALARIOLOGY 1947, June, v 1, No 2, 253-77 Report of a Committee convened for the Co-ordination of Policy regarding the Prevention of Malarial Conditions produced during the Construction of Roads and Railways [COTTER, E, Chairman]

A Committee composed of engineers and malariologists considered memoranda dealing with features in railway and road construction that are likely to create conditions favouring the incidence of malaria, and with the measures that might be taken to prevent such conditions from arising These memoranda are reproduced as appendices to this paper The Committee recommended that the provision of culvert openings under railway and road banks should be more liberal than is the existing practice and should be sufficient to provide for periodic heavy rainfall Culverts should be so designed that a lowering of the invert levels by approximately 5 feet could be effected, if required, without endangering the stability of the structure Borrowpits should be prohibited in built-up areas and for half a mile from their limits Elsewhere, if earth cannot be obtained from another source, specifications are laid down for the construction of borrowpits Adequate provision for their drainage into a natural drainage channel should be made Interconnecting drains between borrowpits should be at least five feet wide, their margins should be kept straight Particular care is required regarding the siting and depth of borrowpits in hilly country on account of the danger of tapping seepage outcrops Adequate drainage should be provided for quarry-pits and cuttings wherever these expose seepage outcrops Measures for the protection against malaria of all persons engaged in railway and road construction should be enforced these measures are

detailed. All engineering projects should make provision for necessary anti-malaria works—a definite proportion of the cost should be earmarked for this purpose.

SKRZULCZAK P. La campagna antimalarica con il DDT nel 1946 nelle provincie venete. Antimalaria Campaign with DDT in 1946 in the Provinces of Veneto. *Riv. di Malariaologia* 1947 Aug. v. 23 No. 4 163-82, maps (1 folding) & 6 charts. English summary

There was a large increase in the incidence of malaria in the Veneto Provinces during the war years. 20,629 cases were reported in 1944-45 as compared with 4,669 in 1938-39. In 1946, I. N. R. R. A. collaborated with the Health Department in a DDT campaign. The greater part of the three most malarious provinces, Rovigo, Venice and Udine, were treated. A 5 per cent. solution of DDT was used for spraying. Some 16,000 houses containing 193,000 rooms were treated between May 6th and August 9th. The malaria morbidity was 50 per cent. lower than in the previous year. Primary malaria infections numbered 1,667 compared with 4,443 during the same period of 1945. The 1946 figure includes cases from some areas that were not treated.

LIVADAS C. A. BELIOS G. D. KOROGLIANXAKI P. & VALLA C. Results of Malaria Control Activities in Greece during 1946 on Basis of Epidemiological Data. *Arch. d'Hygiene* Athens 1947 Apr. Dec., Nos. 4/12, 115-28.

The large-scale anti-malaria campaign with DDT carried out in Greece in 1946 has been described previously (this *Bulletin* 1946, v. 45 492). On the conclusion of that work an extensive survey was carried out in Epirus, Continental Greece, Peloponnese and the Islands with the object of assessing the results achieved. This report gives the result of that survey. In the above areas 5,933 school children were examined to determine the parasite index and 3,910 to determine the spleen index. Blood smears were also taken from 295 babies born between the close of the 1945 malaria season and the autumn of 1946. Of the 60 surveyed areas, 79 had been protected during the 1946 malaria season, in 55 with DDT spray against adult mosquitoes only and in 24 with DDT spray combined with larva control by ground method. Some of the 79 areas also protected by the air-spray programme in nearby swamps. Most surveyed areas were small villages. For the findings in 37 protected areas data of previous years served as a basis of comparison. In these the spleen rates averaged little more than half the previous rates recorded. The parasite rates in 58 protected areas averaged 2.1 per cent. compared with 20.6 per cent., the average of previous recorded rates. In 3 non-protected areas the parasite rates were higher than previously recorded rates. Of 284 babies examined in 26 of the protected areas only one was found infected.

The Malaria Control Service Laboratory in Salonika reported remarkable decrease in the number of positive blood smears examined. Malaria morbidity in the army also showed a remarkable decline compared with previous years.

Norman H. Auld

LIVADAS, G. A. Malaria Control in Greece during 1947. (*Arch. d'Hygiene*) Athens 1947 Apr. Dec. Nos. 4/12, 129-33.

The successful DDT anti-malarial campaign in Greece in 1946 provided experience that was turned to profitable account in 1947. The spraying of houses and outbuildings was started on March 15 and by the end of July 4,617 villages with a population of 2,500,000 had been treated. For houses

an emulsion prepared by mixing one part of a 26 per cent oil solution of DDT with 5 parts of water was used, in the previous year 4 to 5 per cent oil solutions of DDT had been used. This change in the preparation used excited much adverse criticism. For some unexplained reason the house fly was much more prevalent in 1947 than in the previous year, though the control of anophelines and other insect pests appeared to be quite as effective with the emulsion as with the oil solution of DDT. Experiments regarding the resistance of flies to DDT are being undertaken.

The population under protection by the house spray method and larva control with DDT amounted to 4,236 500

HUDSON, J. H. Land Ownership and Anti-Malaria Law in Malaya. *J Trop Med & Hyg* 1948 Feb, v 51 No 2, 33-40 2 figs

BISHOP, E. L. & HINMAN, E. H. Malaria Control Trends on Impounded Waters of the Tennessee Valley. *J National Malaria Soc* 1948, Mar, v 7, No 1, 12-22, 3 figs

In the south-eastern United States the construction of reservoirs results in an increased anophelism which in the past has caused sharp increases in malaria, the vector mosquito being *Anopheles quadrimaculatus*. A system of tributary and main river reservoirs reaches from the headwaters to the mouth of the Tennessee River and drains a basin on which more rain falls than in any area of similar size in the United States, the shore line of these reservoirs exceeds 10,000 miles in length. The production of electric power and flood control are the main objectives of this extensive water project.

Based on wide experience, regulations for malaria control purposes govern the impounding of water and have for their main objective naturalistic or biological control of the vector mosquito by the development of a clear water surface. This entails careful preliminary attention to malaria control measures in the "blue-print" stage so that such measures may be "built in" or form part of the construction scheme, provision must be made for the raising or lowering of water levels. Lastly an effective shoreline maintenance is essential. Water-level manipulation is now so well understood and applied that, together with shoreline improvements, conditions are so unfavourable for mosquito breeding as to bring very much nearer the time when repetitive measures, such as the application of larvicides, may be almost dispensed with.

In the course of reservoir construction the adjustment of the shoreline involves such work as embankment construction, drainage (with or without pumping) of shallow-water areas, and major filling and deepening operations. Where such methods of control are impracticable or uneconomical, recourse is made to the exclusion of human habitations from the area.

After construction is completed, water level management provides control of both mosquitoes and the vegetation which supports their development. This degree of control is attained by a four-phase variation of water level —

1 Late winter or early spring is flood time and the water level is brought to maximum elevation for the purpose of stranding the winter's accumulation of floating debris.

2 From the commencement of new spring growth until the beginning of production of *A. quadrimaculatus*, a constant high level is maintained to prevent the invasion of the mosquito season shoreline levels by fresh vegetation.

3 For some four or five weeks of moderate *A. quadrimaculatus* production, a weekly fluctuation of level operates.

4 The season of heavy *A. quadrimaculatus* production is associated with a seasonal or summer recession of the water levels. The weekly fluctuation

(1 foot) is maintained and in combination with the steady seasonal fall (1 foot per week) the low level of each successive fluctuation cycle results in the water being drawn sufficiently far out of the advancing vegetation growth to ensure adequate control of *Anopheles quadrimaculatus*.

Shoreline maintenance and improvement including control of vegetation by mechanical removal or the use of herbicides, enhances the effect of water level fluctuation. Where larvicides are necessary DDT as an aerosol or fine spray applied by aeroplane has replaced Paris green. DDT applied as a residual insecticide to all buildings and in particular to animal and human habitations, gives greater protection to the population than routine gassing of dwellings.

The progress in the methods referred to above has resulted in a substantial decline in malaria incidence among the populations adjoining the reservoirs of the Tennessee Valley Authority. Malaria prevention better describes the status of the work than does malaria control.

[This paper emphasizes the importance of including the engineering aspects of malaria control measures in the preliminary planning of reservoir construction. In the development of Africa, water projects may well be followed by the intensive malaria associated with *A. gambiae* and *A. f. fuscus* unless similar measures to those of the Tennessee Valley Authority are applied from the beginning of construction. The whole project has now been described in detail in book form (see below p. 822).]

MCCAULEY, R. H., FAY, R. W. & SIMMONS, S. W. The Importance of Coverage in DDT Residual House Spraying for Control of *Anopheles quadrimaculatus* Mosquitoes. Pub. Health Rep. Wash. 1948 Mar 24, v 63 No. 13 401-1 fig.

The experiments were done to investigate the importance of thoroughness in application of residual sprays for mosquito control, with the object of determining whether a time-saving spot treatment could be safely employed. A series of bedrooms were chosen and divided into three groups of three. In one set only the predictable resting places of mosquitoes were sprayed, i.e. underbeds of furniture and pictures, the parts of walls immediately behind them, the corner of rooms and the angles between walls and ceilings (representing about 48 per cent coverage). In another set of three rooms the furniture was removed before spraying and only the walls and ceilings (as in routine jobs) were treated (representing 80 per cent coverage). In the final three rooms, both procedures were adopted (100 per cent coverage).

The insecticide used throughout was a 5 per cent aqueous emulsion of DDT. It was applied with an air pressure hand sprayer to give a residue of about 240 mgm DDT per sq ft. Testing was done after intervals of three, six and sixteen weeks by releasing about 500 laboratory-bred mosquitoes from a cage into each closed room and counting rates of knock-down. The species employed was *An. phaeus quadrimaculatus*.

(1 foot) is maintained and in combination with the steady seasonal fall (1 foot per week) the low level of each successive fluctuation cycle results in the water being drawn sufficiently far out of the advancing vegetation growth to ensure adequate control of *Anopheles quadrimaculatus*.

Shoreline maintenance and improvement including control of vegetation by mechanical removal or the use of herbicides, enhances the effect of water level fluctuation. Where larvicides are necessary DDT as an aerosol or fine spray applied by aeroplane has replaced Paris green. DDT applied as a residual insecticide to all buildings, and in particular to animal and human habitation gives greater protection to the population than routine "guzzing" dwellings.

The progress in the methods referred to above has resulted in a substantial decline in malaria incidence among the populations adjoining the reservoirs of the Tennessee Valley Authority. "malaria prevention" better describes the status of the work than does "malaria control."

[This paper emphasizes the importance of including the engineering aspects of malaria control measures in the preliminary planning of reservoir construction. In the development of Africa, water projects may well be followed by the intensive malaria associated with *A. gambiae* and *A. nesioides* unless similar measures to those of the Tennessee Valley Authority are applied from the beginning of construction. The whole project has now been described in detail in book form (see below p. 822).]

HERR C. G. & CORLISSON F. A Search for the Pre-Erythrocytic Stages of *Plasmodium vivax* and of *P. cynomolgi*. *J. Parasitology* 1947 Dec., 33 No. 6 Section 2 (Supp.) 27

Following upon their successful investigation of the development of avian malaria parasites (this Bulletin 1945 v. 4, 538) the authors made an intensive search for pre-erythrocytic stages of *Plasmodium vivax* in human volunteers. Salivary glands from infected *Anopheles quadrimaculatus* were inoculated in minimum quantities of fluid into the skin, lymph glands, muscle and isolated organs of the volunteers, and biopsies were made of the inoculated areas. No pre-erythrocytic stages were found in biopsies from 1 areas of skin, 7 lymph glands, 4 veins and 1 piece of muscle, although remnants of the inoculum were usually identified. The biopsies were taken in 7 to 150 hours, but mostly at 24-48 and 72 hours.

Biopsies of the inoculated areas were subinoculated or grafted into other volunteers in an attempt to demonstrate viable parasites. Infections developed in all the original recipients of parasites but none in those receiving the biopsied areas of skin.

As pre-erythrocytic stages of some avian malaria parasites will develop in hosts which do not have parasitaemia, attempts were made to find such stages in the areas of inoculation of sporozoites of *P. vivax*—these were made in liver, spleen, bone marrow and skin of 5 species of monkeys, without success. The monkeys in question were *Macaca mulatta*, *Cercopithecus aethiops*, *Cercopithecus a. pygerythrus*, *Cercopithecus fuliginosus* and *Papio papio*.

Negative results were also obtained in the case of similar experiments with *Plasmodium cynomolgi* and the host *Macaca mulatta* at approximately 24-48 and 72 hour intervals in specimens of liver, spleen, bone marrow and skin.

ii. ——— & ——— The Exoerythrocytic Parasites of *Plasmodium cynomolgi* (Demonstration) *Ibid.* 1948 (Discussion 713-16)

i) In a series of earlier notes (this Bulletin 1948, 45 Nos 48, 49) and in a demonstration of pictures at a meeting of the Royal Society of Tropical Medicine and Hygiene on February 19 1948, the senior author and his co-workers have described and demonstrated the pre-erythrocytic schizogony of *Plasmodium cynomolgi* in the liver of monkeys and of *P. vivax* in the liver of man. In the paper under review a further turn is made to the subject and a fuller description of the experimental monkeys and man is given. Two facts showed that the previous view that parasites directly entered red blood corpuscles was incorrect. The first was the remarkable difference between blood-inoculation infections and those produced by parasites. In the former case there is no actual incubation period, as parasites appear quickly in the blood whereas in the latter there is a definite incubation period during which blood inoculated to clean host is non-infective for some days the actual period varying with the needs of parasite. At the end of this incubation period the blood becomes infective and soon afterwards parasites are demonstrable in the blood. The second fact is the difference in the action of drugs on the blood and parasite-produced infections. In blood infections antimalarial drugs may completely retard the infection, while in sporozoite-produced infections the parasites will make their appearance sooner or later in spite of drug. Researchers on

Malaria

Vol 45, No 9]

avian malaria have explained these anomalies by demonstrating the existence and nature of the tissue phase and it became obvious that a similar phase must exist in human malaria. Some observers have actually included it prematurely in descriptions of this cycle of human malarial parasites.

In the experiments, large numbers of *Anopheles maculipennis atroparvus* were fed once, twice or three times on monkeys showing numerous gametocytes in the blood. They were then kept at 25° to 27°C at a relative humidity of over 80 per cent and on a diet of raisins or cane sugar. After a suitable time they were then fed on a clean animal and after feeding they were ground in a mortar in heparinized monkey plasma diluted with an equal volume of normal saline solution. The suspension was then inoculated intraperitoneally or intramuscularly or in both ways into the same monkey. The feeding of the mosquitoes on the monkeys was carried out by anaesthetizing the animals with nembutal and placing them in the cage. The anaesthetic effect lasted 1 to 2 hours, during which the mosquitoes could feed without interruption. The animals so infected were examined frequently, so that the infection could be on the liver. This could be repeated frequently, or a biopsy was performed followed in the same animal. Haemorrhage from the cut surface of the liver was easily controlled by cautery. For fixation of tissues, many fixatives were tried but the best results were given by SHORTT and COOPER (*Trans Roy Soc Trop Med & Hyg*, 1948, v 41, 427)* was used.

The authors describe one of their monkey experiments and the only human experiment.

In the monkey experiment about 1,000 mosquitoes were infected with *P. cynomolgi* by three successive feeds on a gametocyte-carrying monkey. Ten days after the last feed dissection of 20 mosquitoes showed that all were infected. The surviving mosquitoes, 576 in number, were allowed to feed on a monkey. Over 500 fed. The entire batch of mosquitoes was then ground in a mortar and half the suspension was inoculated intraperitoneally and the

*The authors' description is as follows —

This method has the advantage of staining cells and protozoal parasites in tissue sections with colour effects resembling those seen in dry smears stained in Giemsa stain. Details of the technique are as follows —

- 1 Fix in Zenker formal-saline or other suitable fixative
- 2 Embed in paraffin wax and cut thin sections
- 3 Remove wax with xylol
- 4 Remove xylol with alcohol
- 5 Bring down to tap water
- 6 *Treat section with 5 c.c. Lugol's iodine added to 30 c.c. distilled water
- 7 Transfer to 95 per cent alcohol
- 8 Bring down to tap water
- 9 Treat with 0.5 per cent sodium hyposulphite for 10 minutes
- 10 Wash in tap water for 5 minutes
- 11 Stain for 1 hour or longer in Giemsa stain 10 c.c., acetone 10 c.c., methyl alcohol, 10 c.c., buffered distilled water, 100 c.c. (pH 7.2 to 7.4)
- 12 Wash momentarily in tap water
- 13 Differentiate in colophonium resin, 15 grammes acetone 100 c.c. for 15 seconds or longer checking under the low power of the microscope. Renew solution as film forms
- 14 Wash in acetone, 70 c.c. xylol 30 c.c., with several changes
- 15 Apply xylol without draining slide, then apply several fresh changes of xylol until section becomes clear
- 16 Mount in green euparal

*In the case of tissues fixed in non-mercurial fixatives steps 6 to 10 may be omitted

remaining half in two portions into the thigh muscle. Seven days later the monkey was killed and tissues were removed for examination. So far tissue stages have been found only in the liver.

In the human experiment 3,000 mosquitoes were infected with *P. f. s. b.* two successive feeds on a gametocyte-carrier and the mosquitoes were kept at 24–25°C. at a relative humidity of 5–80 and were fed on rabbits. Fourteen days after the last infecting feed the survivors, 2,010 were fed on the volunteer (V.C.) on two successive days. In addition the salivary glands of 200 were dissected in Locke's fluid and were inoculated intravenously. Seven days later a biopsy was performed on the liver to secure, if possible, parasites of six or seven days development.

In the *P. cynomolgi* experiments the earliest forms were seen on the 5th day and the succeeding stages day by day have been found up to the 10th day. The 5th-day stage is a spherical body measuring 10 μ . It has a blue or mottled cytoplasm and purple or magenta-coloured chromatin in irregular masses. The masses followed in serial sections number about 50. The outline of the schizont is clear-cut and stands out in sharp contrast with the cytoplasm of the liver cell. The nucleus of this cell is eccentric, owing to pressure of the parasite, but as a rule is not deformed at this stage while the staining of the cytoplasm and nucleus is faint red.

The 6th-day stage is ovoid and measures 18 μ in longest diameter and contains over 100 nuclear masses. The smooth contour of the parasite at all stages, and whatever its shape, would appear to indicate some kind of pellicle but if this is present it is too fine to be apparent. In some sections the parasite is shrunken leaving a clear space between it and the cytoplasm of the containing cell.

The 7th-day stage is generally ovoid, measuring 31 μ in longest diameter. In some forms the outline is irregular owing to pressure of resistant structures such as fibrous tissue or larger vessels. Some have one or more knob-like arms. The parasites frequently show one or more vacuoles, which may be merely sections across indentations. The cytoplasm is coarsely granular and has a pastel-blue colour. The chromatin masses are magenta colour and are very numerous and fairly uniformly distributed. From serial sections they number from 800 to 1,000.

The 8th-day schizonts resemble the 7th-day form but there is some indication in smears of condensation of cytoplasm round the nuclei. The 9th-day schizonts show some increase in size with average diameter of 35 μ . Some forms 45 μ were encountered.

The 10th-day stage shows considerable change as merozoite formation is complete. Three stages are detectable. In the first, the mature schizont contains merozoites which are kept together by the limiting membrane. Similar forms may be seen on the 9th day. In the next stage the membrane has ruptured and the merozoites are scattered in the surrounding tissue. Each merozoite, consisting of cytoplasm and chromatin measures 11 μ in diameter. With this rupture of the schizont there is an immediate invasion of the parasitic area by phagocytic cells which engulf numbers of the merozoites but some escape and invade the red blood corpuscles. The third stage represents an invasion by the mononuclear cell, polymorphonuclear cell and some plasma cells—which bring about the complete disappearance of the merozoites. These areas of infiltration by cells stand out in the otherwise normal liver tissue. Presumably the phagocytic cells eventually disappear and the area assumes its normal appearance.

In the *P. m.* experiment forms of the 10th and 7th day were found in the liver. The smallest forms seen were of about the 10th day form in the monkey experiment but they are larger being about 4 μ in diameter. The

number of chromatin masses was estimated at 800. Some larger forms were encountered and in some there was indication of merozoite formation. In staining reaction, variations in shape, vacuolation and absence of tissue response, the development corresponded with that of *P. cynomolgi*. One form appeared to represent a rupture of a fully developed schizont and the escape of merozoites. It is not clear whether this is a natural rupture or a mechanical damage to a nearly mature schizont. The merozoites were smaller than those of *P. cynomolgi* and it was not possible to distinguish any cytoplasm. The assumption is made that the rupture was premature. The human subject had been subjected to malaria therapy 22½ months earlier with the same strain of *P. vivax* (Madagascar strain) induced by blood inoculation and had experienced 13 peaks of fever. When the examination of the liver revealed the schizonts it was expected that clinical malaria with parasites in the blood would develop about the 9th or 10th day. In fact there was no clinical attack beyond a transitory rise in temperature on the 15th day, and no parasites were demonstrated in the blood at any time.

In the discussion of these results it is pointed out that the work has provided a solution to the problem of pre-erythrocytic schizogony in mammalian malaria. The *P. vivax* experiment presents an interesting study in immunity. The immunity conferred by the first infection was sufficient to prevent the development of a blood infection, but insufficient to hinder the development of the sporozoites in the liver. There is evidence that a cellular reaction is responsible for the suppression of the blood infection in the invasion of the schizonts of *P. cynomolgi* by phagocytic cells. In fact in the human liver many foci of cell infiltration, often a quarter of a millimetre in diameter, were present. These were not associated with parasites but they probably represented the final attack on pre-erythrocytic forms.

The above account of the pre-erythrocytic development of *P. cynomolgi* commences with a schizont on the 5th day. The complete development is reached on the 8th to the 10th day. The question is raised as to whether the sporozoite requires five days to grow to the size of the 5th-day schizont or whether more than one cycle occurs. While more than one cycle before the fifth day cannot be ruled out, it is assumed that it takes the sporozoite five days to grow to the size of the 5th day schizont. Another unsettled point is the repetition of the schizogony in the liver by merozoites which enter liver cells rather than red blood corpuscles. In avian malaria two types of tissue schizogony occur. One gives rise to small merozoites—micromerozoites—and the other to larger merozoites—macromerozoites. The former are supposed to enter red blood corpuscles while the latter enter cells of the reticulo endothelial system to maintain the exoerythrocytic cycle. The present investigations on *P. cynomolgi* and *P. vivax* have not supplied an answer to these questions. A feature of these liver infections probably explains the failure of other observers to discover the pre-erythrocytic cycle, for HUFF & COULSTON [above], Mammalian Malaria Enquiry [this *Bulletin*, 1947, v 44, 966], SHORTT, GARNHAM and MALAMOS [*ibid* 1948, v 45, 388], and HAWKING, PERRY and THURSTON [*ibid* 1948, v 45, 685], failed to produce infections by the inoculation of suspensions of liver taken from animals in the incubation period.

The paper is illustrated by two coloured plates containing 10 figures of the pre-erythrocytic schizonts of *P. cynomolgi* and 2 figures of the pre-erythrocytic schizonts of *P. vivax*. These show very clearly the process of development described.

11 In the account of the Demonstration the main features of the development of *P. cynomolgi* are described and reference is made to other work on mammalian malarial parasites. The largest of these is *Hepatocystes (Plasmodium) kochi*, which also develops in the parenchyma cells of the liver to schizonts 2 mm. in diameter. It is noted that the earlier stages of this parasite are indistinguishable

short a period. The method would appear to provide a useful screening test for prophylactic activity in human malaria as well as for investigating the mechanism of drug action.

TALLAFERRO W. H. & TALLAFERRO LUCY G. Reduction in Immunity in Chicken Malaria following Treatment with Nitrogen Mustard. *J. Infect. Dis.* 1948 Jan. Feb., v 82, No. 1 5-30 6 figs. [15 refs.]

The authors have previously shown [this *Bulletin* 1948, v 43, 829] that in the case of *P. gallinaceum* and *P. lophurae* infections, exposure to large doses of X-rays may at times reduce immunity possibly through action on lymphocytes and reduction of the amount of antibody formed. The results then obtained have now been compared with those in the same infections in which tri-(3-chloroethyl)-amine hydrochloride (nitrogen mustard) $\text{N}(\text{CH}_2\text{CH}_2\text{Cl})_3\text{HCl}$ was administered. This substance is known to be toxic to lymphocytes and to cause leucopenia, while other nitrogen mustards affect antibody production. The experimental techniques were similar to those employed earlier. The drug was always freshly prepared and was better tolerated by younger than by older birds. One batch of 28 chickens was treated with nitrogen mustard two days previous to and on the day of inoculation with 10 000 blood forms of *P. gallinaceum* while 14 other chickens served as controls. Development of parasites was similar in both groups, but at the peak of parasitaemia infection was more intense in the treated birds. This result was not due to a higher reproduction rate as indicated by the number of merozoites per segmenter or to speeding up of the normal 36-hour asexual cycle which was somewhat asynchronous. A similar experiment confirmed that the infection in treated chickens was more intense but not more lethal.

In chickens treated with the drug 68 to 100 hours after infection, the rate of reproduction was curtailed at one period through reduction in the number of merozoites and all stages of the parasite appeared to be affected adversely. When nitrogen mustard was administered at different stages of the infection after dosage with quinine on the 5th and 6th day following inoculation, given with the object of allowing immunity to develop, the parasitaemia was much more intense than in the control birds. This result appeared to arise from the reduced number of deaths and not from an increase in the reproduction rate. "Nitrogen mustard chiefly damaged the parasitocidal mechanism of acquired immunity. Large doses of drug injured both host and parasite. In the control infections there was a wide variation in the number of merozoites produced per segmenter according to the stage of infection.

When nitrogen mustard was given before inoculation with *P. lophurae* the infections were in general more intense than in the controls. The more intense infection in the case of those receiving the largest doses of drug was not due to increased rate of reproduction and the length of the asexual cycle was unaltered. The greater intensity of infection in birds treated in the prepatent period was likewise not due to increase in the number of merozoites or to a speed-up in the rate of reproduction, but rather to a decrease in the immune reaction of the host. When treatment was given in the patent period the merozoites were reduced in number and the infection was partially suppressed. Differences as well as similarities were apparent in the results obtained on treatment of the two species of parasite. In both cases the drug had a brief parasitocidal effect best seen when it was given during the acute rise of the infection and more marked in *P. lophurae* than in *P. gallinaceum*. A lowering of the immunity of the host as evidenced by an increase in parasitaemia and decrease in death rate of the parasites was the most pronounced

effect produced by the drug and probably arises from the destructive action of the nitrogen mustard on lymphocytes and indirectly by reducing the production of immune bodies

YOELLI, M Antigen common to *Plasmodium* and *Haemoproteus* Amer J Trop Med 1948, May, v 28, No 3, 387-93, 2 figs

" 1 Complement fixation tests were carried out in a group of 146 pigeons
" 2 Positive reactions were obtained in all pigeons with a microscopically diagnosed *H. columbae* infection and in the majority of latent chronic infections The complement fixation test particularly with *P. gallinaceum* antigen was found to be more reliable than direct blood examination for the diagnosis of *H. columbae*

" 3 Antigens prepared from *P. gallinaceum* and *H. columbae* gave specific and group reactions

" 4 The existence of serological cross reactions between the genus *Plasmodium* and the genus *Haemoproteus* was demonstrated

" 5 These results are significant in the light of recent findings of primary tissue forms in *Plasmodium*

REDMOND, W B The Electric Charge of Red Blood Cells in Malaria Science 1948, Feb 20, 199-200, 1 fig

The surface charge on red cells of the blood is stated to be affected in various processes such as agglutination, phagocytosis and inflammation and the author suggests that penetration of red cells by malaria parasites also affects their electrokinetic charge BROWN [this *Bulletin*, 1933, v 30, 830, 1934, v 31, 352], using the blood of canaries infected with *P. relictum*, found that the charge was reduced during the patent period, and for some time after the disappearance of parasites Infected and non-infected cells migrated at the same rate The factors responsible for the reduction in charge were apparently present in the serum The present electrophoretic experiments, in which the cells were suspended in buffered glucose at pH 7.5, were carried out with normal pigeon blood and during infection of pigeons with *P. relictum* In general it was found that as the infection progressed the electrophoretic mobility of the red cells was reduced and even more so after the peak of parasitaemia was passed There followed a slight increase in rate during the sub-patent period Uninfected cells as a rule migrated more rapidly than those which were parasitized, especially when the number of parasites was decreasing but exceptions were sometimes noted when parasites were small During infection with *P. relictum* the charge on pigeon cells therefore appears to be reduced, being smaller on infected than on normal cells The permeability of the cell may thus be altered and would affect the metabolic processes of the parasite as well as the action of antimalarial drugs

HAIBA, M H Plasmodia of Common Egyptian Birds J Comp Path & Therap 1948, Apr, v 58, No 2, 81-93, 6 pls & 12 figs

Blood smears were taken from 22 species of Egyptian birds and were then examined for parasites 62 birds showed infections, 40 per cent with plasmodia and 60 per cent with *Haemoproteus* The species of *Plasmodium* comprised *P. praecox* (*relictum*), *cathemerium elongatum*, *rouxi*, *nucleophilum* and *gallinaceum* These are described and a few minor differences from the classical forms are mentioned *P. relictum* was found commonly in sparrows (up to 80 per cent being infected), also in pigeons, finches, etc The incubation period

was 7-8 days. This species differs from *P. cathemerium* not only in the pigment granules but in relative size. *P. dictum* has schizonts measuring 6.8 to 10 μ with 8-12 merozoites. *P. cathemerium* has schizonts up to 11.9 μ in diameter which produce more than 20 merozoites. The incubation period of the latter species was 4-5 days. *P. onca* showed one unusual feature: some of the rings had a cytoplasmic tail ending in a dot of chromatin (so-called insect net form). The alleged presence of *P. gallinaceum* in a dead fowl of European breed is very difficult to understand. This species is not a primary parasite of the domestic fowl, but of the Indian jungle fowl and the present report requires confirmation before acceptance.

The parasites were studied by subinoculation of citrated blood into healthy birds, but no details are given of the actual transmission experiments. Erythrocytic stages were seen in association with infections with *P. dictum*, *cathemerium* and *elongatum* in reticuloendothelial cells of the brain, liver, spleen and lung—more rarely in the kidney and heart muscle. The presence of *P. longum* in such cells and more remarkable still, in nerve cells in the brain, will need further investigation. The photomicrograph itself is not convincing.

Haemoprocus gametocytes were observed in sparrows, bee-eaters and finches—a second type in pigeons and a third in the black duck, *Anas rubripes trisus*. The parasite in the duck is stated to be larger and to stain more deeply than forms in other birds and to possess large yellow brown pigment granules grouped at the poles of the parasite. The author names it *H. argyria*.

TRY PANOSOMIASIS

GEAR, H. S. African Tse-Tse and Trypanosomiasis Problems. The Brazzaville Conference, 1948. *South African Med. J.* 1948, May 22, v 22, No. 11: 34-4.

The author gives a general account of a conference on tsetse and trypanosomiasis which took place at Brazzaville in French Equatorial Africa in February, 1948. It was attended by British, French, Belgian and Portuguese Colonial Delegates and by delegates from Southern Rhodesia and the Union of South Africa. The author remarks that the present is a particularly suitable moment for scientists to take stock of a group of infections of such immense importance in Tropical Africa. It is evident from the text that the author himself was present at the conference. His article gains in value because it is written by a man with a wide public health experience.

Some of the meetings were devoted to chemotherapy and interesting communications were made including material that has not yet been published. It is evident that both among the arsenical and antimonial compounds there are substances with great curative effect and others which are very poisonous as prophylactics. Attention was called to the striking differences, in results of therapy of infections with *T. bruceense* and *gambiense* (the view was expressed by FAIRBRIDGE that in *brucei* infections treatment is only effective if it is given within four weeks of the infection).

Two territories reported on organized human settlement as a method for the control of tsetse and trypanosomiasis. In Tanganyika there are many thousands of people settled in a swampy country which was formerly occupied by *G. morsitans*. It has been found necessary to settle the population on a considerable compact area and at such a distance as to allow man to occupy all parts of the area when this is done the frontier between culture and bush is definite and as short as it can be and thus reduces the contact between man

and fly At Anchau in Nigeria there is an area about 70 by 10 miles in which sleeping sickness was formerly very severe owing to *G palpals* and *tachnoides* Steps were taken to exterminate these flies by a limited degree of waterside clearing and there are now fifty thousand people with many cattle in the area During the course of the work much has been done to improve standards of village life, new crops and better farming methods have been introduced together with greatly improved types of housing and layout of villages It is clear that this use of organized human settlement demands a very good understanding not only of fly and bush but also of local agriculture and the habits of the villager In skilled hands it is evidently valuable and it leads to permanent general improvement

The conference also reviewed a number of other methods for controlling various species of tsetse such as discriminative clearing, the use of new insecticides and the control of game

The conference recommended that a standing scientific committee of experts should be set up to provide for international discussion on the progress of research on tsetse flies and trypanosomiasis The French and Belgian authorities were invited to set up a bureau to collect and disseminate information

The author concludes with the hope that these features may ultimately be integrated with other measures for improving the health of tropical Africa as a whole

CHORLEY, T W *Glossina pallidipes* Austen attracted by the Scent of Cattle-Dung and Urine (Diptera) *Proc Roy Entom Soc of London* Ser A 1948, Mar 18, v 23, Pts 1/3, 9-11

As the result of much experience in Uganda with several species of *Glossina* the author feels that tsetse flies are guided by their sense of smell more than is generally supposed

He has observed that *G morsitans* does not congregate in places through which elephants have passed but it does congregate where they have rested, even a day or two previously He has made similar observations with *G pallidipes* and buffalo he also notices that several species of tsetse flies tend to haunt the places where hippopotomus lie up on shore, which are deep in dung These observations lead the author to his view that *Glossina* of several species haunt places where there is a strong animal smell

Chorley has tested this view experimentally, bringing in quantities of cattle dung to places where there were no cattle, and erecting small shelters to protect it from rain, other shelters without dung were put up as controls When arrangements were made to catch *G pallidipes* round the several shelters, it was found that the numbers were consistently greater round those in which dung had been placed than round the others the difference could be observed even after six weeks when the observer could no longer detect any smell

CECCALDI, J, TRINQUIER, E, POCHARD, P & VARGUES, R Resultats du traitement de la trypanosomiase humaine par le compose 70 A ou para-arséno [The Treatment of Human Trypanosomiasis with 70 A] *Bull Soc Path Exot* 1947, v 40, Nos 11/12, 439-44

The authors give details of disappointing trials of *p*-arsenosophenylbutyric acid against *T gambiense* sleeping sickness [for earlier reports and other references, see Report of Brazzaville Pasteur Institute for 1944 this *Bulletin*, 1947, v 44, 45, and EAGLE, this *Bulletin*, 1946, v 43, 1017]

Treatment was given intravenously and daily for periods varying from 7 to 21 days, the individual dose being 0.4 mgm. per kgm. in 63 cases, and 0.3 mgm. per kgm. in the remaining 4 of the total number treated. Trypanosomes usually disappeared from the gland juice or blood within 15 minutes of the first injection but of patients in the lymphatic-blood stage only 2 out of 10 treated for 7 days, and only 17 out of 32 treated for 11-20 days, were provisionally cured 6 or 7 months after treatment.

All cases treated in the later stages of infection became worse with only 1 exception and combined treatment with "para-ars no." and trypanazole in this type of case gave results inferior to those associated with established forms of treatment.

FIGURE 1. The Persistence in the Blood Stream of some Compounds related to Suramin. Biochem. J. 1948, 4, No. 1 109-116 4 figs. [41 (a)]

It was observed soon after the introduction of Suramin (also known under many other names Bayer 205 Germanum Antypol, Moranyl etc.) that the drug persisted over long periods in the body as shown by prophylactic action, the trypanocidal effect of the serum of treated animals and by chemical methods. There does not appear to be any particular tissue which acts as a storage depot since the concentration in plasma is as high as in tissues. The substance has been shown capable of combining with different types of protein with it is possible that it exists as large colloidal particles in solution which prevent easy passage through the kidney glomerulus in the same way as passage is prevented through a colloidal membrane. It seems possible that Suramin bears similar in structure to a natural polypeptide might undergo hydrolysis to its component parts in the body. DAWY & WORTSALL (this Bulletin 1944 43, 830) showed, however that unlike the parent substance the product of acid hydrolysis was readily eliminated. Partial hydrolysis may offer an alternative explanation of its persistence in the body. The present author has investigated the persistence in the rabbit of Suramin and seven other substances either closely related to it or potential products of its hydrolysis in order to obtain information on the structural features which endow it with its special properties and also to find out whether they are correlated with activity. The persistence shown by possible hydrolytic products should all serve as a guide to whether they are actually formed in the body. The method of estimation of these substances in plasma depends on diazotization and coupling reactions based on methods previously used by the author (1947). Results in terms of experiments are tabulated approximately 10 per cent for the purposes of estimation, alkaline hydrolysis for period 18 hours was invariably used since normal plasma gave smaller blanks by this procedure than if acid hydrolysis was used. In the best of the test about 10 per cent of the drug, in doses of 11.5 mgm. per kgm. Plasma was sent two times at 15 min. after treatment for all the compounds. The first in plasma of Suramin and closely related compounds was still high after 5 days. The least persistent compounds were completely eliminated within a few hours while the others showed persistence intermediate to that of these two groups. Marked persistence was found to be a characteristic of 4 amides of high molecular weight having naphthylammonium sulphonic acids other than aryl sulphonic acid groups. Their proteic activity and capacity were not related to the naphthylammonium groups but were eliminated fully and it was also proved that Suramin is resistant to hydrolysis and other water soluble groups.

[This is an interesting paper which should be consulted in the original by those interested in order to appreciate the relationships between the various compounds tested] J D Fulton

TAYLOR, Jane & BECKER, E R Liver Changes in Pantothenate-Deficient Rats infected with *Trypanosoma lewisi* *J Infect Dis* 1948, Jan-Feb, v 82, No 1, 42-4, 4 figs

Young rats fed on a standard diet deficient in pantothenic acid are capable of developing unusually heavy infections of *T lewisi*, with associated pathological changes. These changes are attributed by the authors to the enhanced parasitaemia rather than to the dietary deficiency, since the latter alone produces only moderate effects. The deficiently fed infected rats weigh much less than normal, with proportionately decreased liver weight, but their spleens become heavier in proportion to body weight to a greater extent than in the case of infected animals fed on a normal diet.

Trypanosomes were found not only in the Kupffer but also in the parenchyma cells of the liver. Agglomerated masses of trypanosomes, which normally appear in infected rats from the 10th to 14th day of infection with *T lewisi*, were not seen in the blood or in organ smears from infected animals fed on the deficient diet. In specimens examined from animals on a normal diet it was noted that these agglomerations were significantly more frequent in liver impression slides than in blood smears. A possible explanation is that the liver sinusoids exercise a screening effect. E M Lourie

ERCOLI, N & WILSON, W Influence of BAL on the Toxicity and Chemotherapeutic Activity of Mapharsen *J Pharm & Exper Therap* 1948, Feb, v 92 No 2 121-6

BAL reduces the toxicity of arsenicals and of certain other metallic compounds. The question therefore arises whether it interferes also with their chemotherapeutic activity, and the authors have investigated this question by experiments in which mice infected with *Trypanosoma equiperdum* were treated concurrently by mapharsen and by BAL.

It was found that BAL does, in fact, interfere substantially with chemotherapeutic activity under these experimental conditions. The interference is greater where the criterion of chemotherapeutic effect is sterilization than where it is mere temporary disappearance of trypanosomes from the circulating blood.

Toxicity to the host is influenced by BAL much less than chemotherapeutic effect, thus, the amount of BAL compared with mapharsen necessary to interfere with toxicity was found to be 1.0-2.7 times as much, whilst doses of BAL as low as $\frac{1}{4}$ of the mapharsen weight can interfere with the sterilizing (i.e. curative) effect.

The authors conclude that their findings establish the unsuitability of this form of combined chemotherapy. E M Lourie

CHEN, G Effect of Arsenicals and Antimonials on the Activity of Glycolytic Enzymes in Lysed Preparation of *Trypanosoma equiperdum* *J Infect Dis* 1948, May-June, v 82, No 3, 226-30, 3 figs [11 refs]

"Mapharsen, stibamine and tryparsamide were shown to inhibit the activity of hexokinase, adenosine triphosphatase and 3-phosphoglyceraldehyde dehydrogenase systems in lysed *T equiperdum*."

"The inhibition may be antagonized by cysteine."

produced by intraperitoneal inoculation of a suspension of infected spleen, and the disease (which is symptomless in the cotton rat) progressed regularly with no tendency to spontaneous cure. The animals did not die, however and in this way differed from hamsters, which invariably succumb to leishmaniasis. The spleen became enormously enlarged and contained numerous parasites—the liver equally so during the early stages. The infection did not pass to the offspring of diseased mothers. Orlney voles were insusceptible.

MEXER J & MEDINA, H. Leishmaniose tegumentar do cobaiá. *Leishmania curatilis* n. sp. (Cutaneous Leishmaniasis in the Guinea-pig.) *Hospital*. Rio de Janeiro. 1948, Jan. v 33, No 1 7-5, 10 figs. English summary

Since at present, the species of *Leishmania*, *L. curatilis*, with which this article is concerned appears to be almost restricted to the guinea-pig, the subject is one of comparative pathology, mainly and does not call for a very detailed account. The reasons for mentioning it here are that it is a species easily cultivated, that guinea-pigs are readily infected, experimentally as well as spontaneously, and that it may be used for testing therapeutic substances. Subcutaneous inoculation of material from lesions or from cultures invariably sets up the disease in guinea-pigs, but very rarely does so in other animals. Rhesus monkeys, hamsters, dogs, white rats and mice were heavily inoculated but only one hamster (*Cricetus auratus*) and one puppy showed any leishmanial lesions and they were small and seemed to be regressing. The preá (*Canis sferus*) known also as the Brazilian opossum and closely allied to the guinea-pig, could not be thus infected. Reciprocally the guinea-pig is resistant to infection with *L. tropica* and *L. donovani*. The morphological characters of *L. curatilis* are described in detail.

H. Harold Scott

TORRES, C. M. MEXER J. CARDOSO Rita L. de A & DUARTE, Elitel. Caracteres do granuloma histiocitário na leishmaniose espontânea do cobaiá. [The Histological Characters of Leishmanial Granuloma of the Guinea-pig.] *Hospital*. Rio de Janeiro. 1948, Mar. v 33 No. 3 403-8, 3 figs. English summary

One of the most characteristic features of infection of guinea-pigs by *L. curatilis* is the production of a granuloma consisting largely of histiocytes and macrophages enclosing many of the parasites in their cytoplasm. Equally characteristic are the readiness and rapidity with which these cells become transformed into fibroblasts and may then be diagnosed as fibromata or even more commonly, as spindle-celled sarcomata—pseudo-neoplasms, as the authors designate it (though why pseudo is not clear unless the term neoplasm is restricted to malignant growths). Three photomicrographs show the condition well and from the third it can easily be understood how confusion might arise and a diagnosis of fibro-sarcoma be made.

FEVERS OF THE TYPHUS GROUP

HAYDON, M. Clinical and Serologic Observations during a Typhus Fever Epidemic. *Ann. Med. Intern. Fen* 1948, 37 No 1 51-60 [14 refs.]

In one section of a hospital for prisoners of war 32 cases of typhus fever occurred within a period of six weeks. In five of the cases the Weil-Felix reaction remained negative throughout the illness and in all but one of the

remaining cases the reaction became negative within nine weeks of the end of the illness. A positive reaction with the Widal test occurred in 12 cases. The fatality rate was 44 per cent.

John W D Megaw

WANG, P J, FU, H H & LIU, W T. A Note on Typhus Fever in Lanchow. *Chinese Med J* 1948, Feb, v 66, No 2, 79-83

During the three years 1943-1945 the authors studied 131 cases of typhus fever at Lanchow in North-West China. The epidemiological conditions pointed to louse-borne infection.

Three strains of rickettsiae were isolated, these caused frequent Neill-Mooser reactions during ten consecutive passages through guinea-pigs but examination of the strains by the U.S.A. Typhus Commission workers at Caro showed that they gave complement-fixation and immunity reactions indicating epidemic-typhus infection.

Local house rats and their fleas were examined, but no evidence of infection could be detected.

Nota prévia [A Preliminary Note on the Possibility of the Transmission of Epidemic Typhus by Milk in Brazil] *Brasil-Médico* 1948, Apr 3 & 10, v 62, Nos 14/15, 153-4, 1 fig.

GIROUD, P & JEZISKI, A. Comportement sur poumon de lapin du mélange du virus aphteux O et des rickettsies du typhus épidémique [The Effect of Lung Inoculation of the Rabbit with a Mixture of the Virus O of Foot-and-Mouth Disease and Epidemic-Typhus Rickettsiae] *C R Soc Biol* 1947, Dec, v 141, Nos 23/24, 1181-2.

In the course of their studies of the virus of foot-and-mouth disease the authors carried out experiments on the effect of lung inoculation of rabbits with a mixture of the virus and epidemic-typhus rickettsiae.

By the end of five successive passages the rickettsiae had died out, whereas the virus continued to be transmitted.

FRANKE, R. Die Weil-Felixsche Reaktion nach Fleckfieberschutzimpfung, [The Weil-Felix Reaction after Anti-Typhus Inoculation] *Klin Woch* 1947, Sept 15, v 24/25, Nos 47/48, 746-9, 1 fig.

Weil-Felix tests were carried out on a group of 60 persons before and after inoculation with three doses of yolk-sac, mouse-lung, or rabbit-lung vaccine. Four to five days after the third dose a titre of 1-100 was observed in 50 per cent of the cases, in 10 per cent the titre rose to 1-400, and in two cases it was 1-800. In 10 per cent no rise of titre could be detected. In a few cases the test was repeated three weeks after the last dose of vaccine, and in nearly all of these the titre had fallen to an appreciable degree.

BLAKE T O Employment of Soluble Antigen in Screening Tests for Typhus Complement Fixation. *Pub. Health Rep. Wash.* 1948, Apr 23, v 63, No 17 529-37 [13 refs.]

Soluble antigens liberated from suspensions of *Rickettsia prowazekii* and *R. mooseri* by ether extraction are known to be incapable of differentiating between epidemic and murine types of infection, but they have great practical advantages over the more specific purified antigens in being easily and cheaply prepared.

The author describes the technique by which he has prepared the soluble antigens from several strains of epidemic and murine rickettsiae. He has employed the strains in complement fixation tests of antisera obtained from guinea-pigs infected with different strains of rickettsiae. The same antisera were also tested with specific purified antigens prepared from the strains of rickettsiae used in the above tests. It was found that soluble antigens prepared from any of the strains of epidemic and murine rickettsiae gave positive reactions with every strain of antiserum and that the reactions were usually at higher titres than those obtained with specific antigens, even when the latter were prepared from homologous strains of rickettsiae.

Further tests were carried out on 475 sera of presumably healthy persons from Korea and Japan. 47 of the sera were anticomplementary. 169 reacted at titres of 1/10 to 1/60 and of these 72 were positive also with epidemic or murine specific antigens or with both. In no case did a serum react with a specific antigen when it had not already reacted with soluble antigens of every strain used in the tests, and in only six cases was the reaction with the soluble antigen at a lower titre than that with the specific antigen.

It was concluded that in diagnostic and survey work a preliminary set of screening tests with soluble antigen, either epidemic or murine, would greatly diminish the number of tests that would have to be carried out by the troublesome and costly employment of the purified specific antigens.

HENNER, K. Über die Behandlung des Fleckfiebers. [The Treatment of Typhus Fever] *Alim. Woch.* 1947 Nov 1 v 24/25 Nov. 53-54 848-50.

Since 1941 the author has had experience in the treatment of more than 1,000 typhus patients in a large war hospital in the "East".

An analysis is given of the results observed in 900 acute cases seen between October 1941 and March, 1944. Dividing the 900 cases into six equal groups in chronological sequence it was found that the fatality rate showed a remarkable decline. In the first group treated in the winter of 1941-42 the death rate was 36.3, in the next two groups it was 16.7 per cent, and in the last two it had fallen to 8.0 per cent.

The author admits that this striking improvement certainly cannot be attributed solely to better methods of treatment, but he claims that his latest system deserves wide publicity because of the remarkably good results that were obtained.

Drugs claimed to be specific including atabrin, plasmoquine, cubanin, cibazol and pyramidon, are regarded as useless, sometimes dangerous. Convalescent serum when given after the third day was without value.

The secret of success is claimed to consist in the administration of cardiovascular tonics and sedative drugs when and only when there are indications that these are needed. Threatened vasomotor collapse is treated by such drugs as camphor, caffeine, strychnine, adrenaline and strophanthidin, and by intravenous saline. For severe headache, insomnia and restlessness morphine, luminal and veronal are recommended.

In the winter of 1944, a number of patients who came under treatment on the second or third day were at once given 500 cc of convalescent blood and the results observed are said to have been startling, but little information is given with regard to the number of cases treated or the evidence on which so early a diagnosis was made. The author simply states that the symptoms and circumstances of cases left no room for doubt as to the nature of the illness

EHRlich, J, BARTZ, Q R, SMITH, R M & JOSLYN, D A **Chloromycetin, a New Antibiotic from a Soil Actinomycete** *Science* 1947, Oct 31, 417

A *Streptomyces* sp was isolated from a soil sample in a field near Caracas, Venezuela. Agar streak cultures were found to inhibit inocula of numerous common Gram-positive and Gram-negative organisms. Filtrates of submerged aerated cultures of the *Streptomyces* showed marked antibacterial activity against several Gram-negative bacteria, especially *Sh sonnei*. A crystalline antibiotic has been isolated from the filtrates and the name Chloromycetin is proposed for it. Details of preparation are described. The *in vitro* activity of the crystalline product against several bacteria is shown in a table. The intravenous LD₅₀ for 20 gm mice is 3.0 mgm/mouse. Chloromycetin, unlike streptomycin, appears to be well absorbed when given orally to mice and dogs.

The immediate interest of this new antibiotic to readers of this *Bulletin* lies in its indications of antirickettsial activity [see below]

H J O'D Burke-Gaffney

SMADeL, J E & JACKSON, E B **Chloromycetin, an Antibiotic with Chemotherapeutic Activity in Experimental Rickettsial and Viral Infections** *Science* 1947, Oct 31, 418, 1 fig

The authors describe tests on chick embryos and mice infected with *R orientalis* and have found the drug highly effective. Mice treated with suitable doses either by the intraperitoneal or oral route were completely protected against lethal doses of infection. For example, daily doses of 2.5 cc of the drug given by the intraperitoneal route saved all the eight mice whose treatment was started five days after infection. Daily doses of 5.0 mgm given by the mouth saved seven out of eight mice whose treatment was started two days after infection.

Similar results were obtained with chick embryos infected with *Rickettsia akari* (of rickettsialpox), *R prowazeki*, *R mooseri*, *Dermacentroxenus rickettsi*, and two strains of psittacosis virus. Mice infected with *R akari* were treated with similar success

John W D Megaw

PAYNE, E H, KNAUDT, J A & PALACIOS, S **Treatment of Epidemic Typhus with Chloromycetin** *J Trop Med & Hyg* 1948, Apr, v 51, No 4, 68-71, 2 figs & 2 maps

Chloromycetin had already been found effective in preventing the death of embryo chicks infected with various rickettsiae, including *Rickettsia orientalis*, *R prowazeki*, *R mooseri*, and *R rickettsi* [see above]

The authors describe clinical trials of the drug during an epidemic of typhus fever in Bolivia in December, 1947. It is stated that 16 cases of typhus and 'five normal controls' were treated, and that six of the cases were adequately studied and followed up.

The report consists of a description of one fatal "control case," and of six of the treated cases in which all of the patients are said to have shown rapid improvement, resulting in convalescence within three days.

The drug was given orally to four of the patients in doses of 0.5 to 1.0 gm. twice daily for three days, and intravenously to the other two patients, aged 17 and 14 years respectively, in doses of 0.2 and 0.25 gm. twice daily for three days. No toxic reactions were observed.

[Although the results as described do not lend themselves to a definite evaluation of the effects of the drug they justify further trials which, if possible, ought to be carried out in conditions permitting comparison with alternate controls, either untreated or treated with para aminobenzoic acid.]

RICHARD, E. R. & RILEY, E. G. A State-Wide Survey of Typhus Fever in Florida. *Amer J P & Health*, 1948, 4yr v 38, N 4 541-9, 3 charts & 1 map.

The name typhus fever is employed in the title of this paper as a designation for murine typhus. A description is given of a detailed survey of the incidence of the disease in the State of Florida during the three years, 1944-1946.

About 69 per cent. of the population (2,250,000) lived in urban conditions in towns of 1,000 inhabitants and over. The officially reported numbers of cases for the three years were 493, 380 and 420, respectively, but the real numbers were estimated as being at least 1,234, 1,045 and 793. Personal investigations were made in about two-thirds of the cases.

The distribution was comparatively uniform throughout the State, the rural population was nearly as heavily affected as the urban. The incidence was considerably higher among the white than the coloured population and among adults than young children, but the authors believe that many cases occurring in coloured persons and children are likely to have been missed.

During the period, 1,337 cases with positive or doubtful Weil-Felix reports from State and private laboratories were investigated. 1,038 of these had given reactions at titres of 1,320 or over and in 95 per cent. of this group the diagnosis was considered to be justified on clinical grounds. Among the 299 cases with reactions at a titre of 1:160 the diagnosis was confirmed in 73 per cent.

In 67 per cent. of the cases, infection was believed to have been acquired in the homes. In 28 per cent. places of business were considered responsible, and about two-thirds of these were concerned with food handling. In the remaining cases no opinion could be formed with regard to the place of infection.

There was a sharp decline in the incidence during the period in the two regions in which control measures were being carried out.

LEON, J. V., MURPHY, J. N., Jr & DAVIS, D. E. The Distribution of Endemic Typhus in Rats in Lavaca County Texas. *Pub Health Rep Wash*, 1948, May 1 v 63 No. 21 697-4.

"Based on results of complement fixation tests for endemic typhus of rats in Lavaca County, Texas.

"1. Ninety-four percent. of 10 urban establishments sampled harbored rats with positive tests. Of 47 *Rattus norvegicus* from urban establishments, 61 percent. gave positive tests and 134 *Rattus norvegicus* 69 percent gave positive tests.

"2. In rural or semirural areas 77 percent. of 243 farms or semi-rural establishments harbored rats with positive tests, and 44 percent. of 523 rats gave positive tests.

3. The widespread distribution of typhus in rats on farms suggests that such rats must be included in control activities.

FITZPATRICK, Florence K. **Susceptibility to Typhus of Rats on Deficient Diets.**
Amer J Pub Health 1948, May, v 38, No 5, Pt 1, 676-81

Groups of 12 or more rats were kept for six weeks on various diets planned so as to imitate deficiency diets such as exist or might occur in different parts of the world. Then two-thirds of the rats in each group were inoculated intraperitoneally with varying doses of murine-typhus rickettsiae. In some of the experiments the infecting doses were lethal to 50 per cent of normal rats, in others the doses were sublethal.

The susceptibility of the rats was found to be increased by diets deficient only in one of the following respects (1) low proteins, (2) one-tenth of the optimum supply of vitamins of the B group, (3) reduced pantothenic acid, (4) reduced riboflavin, and (5) reduced thiamin.

Rats kept on diets deficient only in containing one-fortieth of the optimum amount of one of the following substances: pyridoxine, choline, nicotinic acid, and para-aminobenzoic acid were not affected. With a similar reduction in the amount of thiamin, pantothenic acid or riboflavin, premature deaths occurred among the rats.

The addition of one per cent liver powder to the complete diet did not increase the resistance of the rats to infection.

An interesting point was that rats kept on a natural laboratory diet were decidedly less susceptible to infection than those kept on a complete synthetic diet, even though the latter caused a greater increase in weight.

Full details of the diets employed and of the results of the experiments are given in the paper.

DUNN, T B. **A Case of Murine Typhus in London** *Brit Med J* 1948, May 22, 979-80

A Jewish patient aged 61 years, who had emigrated from Western Russia 36 years ago, was attacked by typhus fever in June, 1947.

A fortnight before the onset he had been engaged at the London Docks in testing eggs belonging to a cargo that had arrived from Poland. He said that he had frequently been bitten by fleas while at work. A search was made for rats in the area but none could be found. There was no evidence of louse infestation.

The Weil-Felix (OX19) titre was 1-125 on the 11th day and 1-500 on the 14th day. With the rickettsia-agglutination test, a titre of 1-2,560 was observed with murine rickettsiae and one of 1-640 with epidemic rickettsiae.

Infestation of the egg packing cases with infected fleas was suspected of being the source of infection. In spite of the patient's having lived in Russia till the age of 25, the diagnosis of Brill's disease is regarded as very unlikely. A further report on the serological findings is promised.

SAVOOR, S R & DAS MENON, P, in collaboration with S M MERCHANT
Scrub Typhus (Tsutsugamushi Disease) in Bombay *Indian Med Gaz* 1948 Dec v 82, No 12, 752-6, 1 fig on pl [13 refs]

Four cases of scrub typhus are described as occurring in persons who had not gone outside the municipal limits of Bombay City during the four weeks preceding the onset of the attacks. In two cases there was an eschar, and in one case *Rickettsia orientalis* was isolated from a patient's blood by mouse inoculation and by intraocular inoculation of rabbits.

The authors think that three of the patients had probably been infected through contact with mite-infected coarse vegetation. In the fourth case the only possible source of infection seemed to be the handling of vegetables.

All the cases occurred during and after the rains (June to December 1945) and in a footnote SOMMER states that he has detected 17 cases of scrub typhus in Bombay during the months September, October and November 1946. *R. orientalis* was isolated from seven of the patients. No cases occurred during the other months of the year although the system of detection was the same throughout the period.

John W. D. Macgregor

FINDLAY G. M. & ARCHER, G. T. L. The Occurrence of Tick-borne Typhus in West Africa. *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948, May v. 41, No. 6, 813-18, 1 chart.

Three cases of typhus fever diagnosed on serological evidence as tick borne occurred during the last three months of 1943. The patients were Europeans living in military camps—two of them were stationed in North Ishantl and appear to have been the persons referred to in a paper by FINDLAY and ELKES (see this Bulletin 1948, v. 45, 322)—the third patient was living on the Jos Plateau in North Nigeria.

The chief evidence pointing to tick borne infection is stated as being the absence of complement fixing antibodies and agglutinins for murine and epidemic typhus and the presence of antibodies for South African tick typhus. In one case rickettsiae were isolated from the patient's blood and passaged twice through guinea-pigs, in which some inflammation of the tunica vaginalis occurred. This patient's blood gave a Weil-Felix reaction with the slide test against *Proteus OX* but not against *P. OX19* or *P. OXA*; the complement-fixation titre against epidemic and murine antigens was 1-50 against South African tick typhus it was 1-400.

In the other two cases the epidemic and murine titres were 1-50 and 1-12.5 respectively; the tick-typhus titre was 1-200 in each case.

VILES J. O. & BOCKHE G. C. The Use of Para-Aminobenzoic Acid in a Case of Rocky Mountain Spotted Fever. *New England J. of Med.* 1948, May 27, v. 238, No. 22, 69.

"A case of Rocky Mountain spotted fever treated successfully with para-aminobenzoic acid is presented. No toxic effect to the drug were noted."

WEGMANN T. Leber eine Q-Fever (Queenslandfeber)—Epidemie in Granbuden. [An Epidemic of Q Fever in Granbuden (Grisons, Switzerland).] *Schweiz. med. Woch.* 1948, June 5, 78, v. 22, 529-31, 4 figs.

In April 1947 19 cases of Q fever occurred among 75 persons who had been engaged in unpacking and erecting a large printing press which had arrived from Cincinnati, Ohio, packed in straw in several wooden packing cases. The work of unpacking and erecting took four days and it was obviously during this period that infection occurred. The average incubation period was estimated as about 18 days, the extreme range was 9-23 days.

The nature of the disease was not recognized till nine months after the occurrence of the outbreak, when complement fixation tests against an American strain of *Rickettsia burnetii* gave positive responses in the 18 patients whose sera were obtainable. The titres ranged from 1-10 to 1-320. The diagnosis in most of the cases had been influenza or fever of uncertain origin.

Infection was believed to have been due to the inhalation of infected dust from the straw contained in the packing cases.

John W. D. Macgregor

STRAUSS, E & SULKIN, S E **Studies on Q Fever Complement-Fixing Antibodies in Meat Packers at Fort Worth, Texas** *Proc Soc Exper Biol & Med* 1948, Feb, v 67, No 2, 139-41 [Refs in footnotes]

Sera from 1,443 persons engaged in handling meat at plants in Fort Worth, Texas, were tested by Bengtson's method for complement-fixing antibodies of *Rickettsia burneti*. Positive reactions at titres of 1-8 or over were obtained in 114 cases (8 per cent), including 17 cases (1.2 per cent) in which the titre was 1-64 or over.

These results were regarded as showing that some unrecognized attacks of Q fever had occurred among the persons examined.

Further studies are in progress to find whether the antibodies occur among persons belonging to other occupational groups in the area.

John W D Megaw

SULKIN, S E & STRAUSS, E **Studies on Q Fever Persistence of Complement-Fixing Antibodies after naturally acquired infection** *Proc Soc Exper Biol & Med* 1948, Feb, v 67, No 2, 142-4

Sera from 17 persons known to have had naturally acquired attacks of Q fever in March, 1946, at Amarillo, Texas, were tested at later dates for complement-fixing antibodies of Q fever.

All the sera gave positive reactions five to seven weeks after the attacks, in the 11 cases in which the titre was estimated it ranged from 1-64 to 1-1,024.

Among 13 sera tested six months after the attack, 10 gave titres of 1-32 or over, the other three gave titres of 1-16, 1-8, and less than 1-8, respectively.

Seven sera were tested 17 months after the attack, all were positive at titres of 1-16 or over, including one at 1-128 and one at 1-1,024.

It was thought possible that the person who reacted at 1-1,024 may have had "continued contact with the rickettsial agent subsequent to the initial illness."

ASCHENBRENNER, R **Pathogenetische und therapeutische Probleme beim Wolhynischen Fieber** [Pathological and Therapeutic Problems of Trench Fever] *Klin Woch* 1947, May 15, v 24/25, Nos 31/32, 481-8, 7 figs [57 refs]

The paper contains a critical review of the literature dealing with trench fever as observed during the two World Wars, and a brief description of a few cases seen by the author in 1942 and 1943.

Most of the papers discussed have already been reviewed in this *Bulletin*. The author is very sceptical regarding the value of the numerous special lines of treatment that have been recommended by German physicians. He specially condemns the light-hearted use of injections of bacterial toxins and mentions a case of sudden death after an injection of "Pyripher" given intravenously. He also states that another patient died suddenly after an intramuscular injection of prontosil. He states that an independent trial has failed to substantiate the claims made by HESSE and KREMSER for X-ray therapy in chronic cases, but in a later issue of the same journal [see below] Hesse asserts that the author when challenged was unable to produce satisfactory evidence with regard to the nature of the trial.

The paper conveys the impression that surprisingly few additions have been made during the recent war to knowledge of trench fever.

DENGUE AND ALLIED FEVERS

- PERRY W. J. The Dengue Vector on New Caledonia, the New Hebrides, and the Solomon Islands. *Amer J Trop Med* 1948, Mar v 28, No. 2, 53-9 (10 refs.)

It has been known for some years that dengue occurs in those parts of Melanesia to which the paper refers. In this area, *Aedes aegypti* occurs as a relatively recent introduction limited to areas round ports and places where Europeans live. In such places dengue occurred and the author concluded that it was carried by *Aedes aegypti*. He also gave attention to the possibility that it might be carried in completely rural areas by members of the *Aedes scutellaris* group. Of these, *Aedes hebrideus* is widely distributed in the area, breeding in small rot holes etc., in the forest and biting man freely. The author could find no evidence of the occurrence of dengue in such areas. As he observes, his experience is different from that of MACHERRAS in New Guinea (see this *Bulletin* 1947 v 44 518). In that island, sporadic outbreaks of dengue occurred in rural areas, in the absence of *Aedes aegypti*; the virus was passed through the bite of *Aedes hebrideus* to healthy volunteers.

PLAGUE

- MALTA. REP. ON HEALTH CONDITIONS OF THE MALTESE ISLANDS AND WORK OF MED. & HEALTH DEPT. FOR YEAR 1945. CAUCCI, J. Chief Govt. Med. Officer. Appendix III. pp. 1571-92. Report on the Outbreak of Plague 1945-48.

Early in 1945 plague had already appeared in the port of Algiers, Oran, Haifa, Jaffa, Ferryville and the Suez Canal Area, spreading later to Ajaccio, Tarant, Palermo and Rhodes. In Malta it broke out at the same time as in Ajaccio. Altogether 80 cases of bubonic plague made up the epidemic, none was pneumonic and only one septicaemic. The epizootic that occurred in rats was widespread and human cases were soon recorded from different localities with the result that bubonic plague was notified as existent from June 1945. The course of the epidemic followed in this report month by month up to June 1948 with a total of 22 deaths and case mortality rate of 77.5 per cent. Both epidemic and epizootic seem to have subsided, for no infected rats have been detected since 1 January 1947. The rat poisons used in combating plague were zinc phosphide and arsenic.

W. F. HARRIS

- HADDAD, C. & VALEAU, A. Streptomycin in Bubonic Plague. *Brit Med J* 1948, May 29 1078-7

Three severe cases of treated bubonic plague and one control untreated as not a large number. They are published as being sufficiently dramatic to suggest that streptomycin is superior to any drug that has preceded it in

regular use In the three cases treated with streptomycin (200 or 300 mgm every 3 hours) both sulphonamides and penicillin had been without effect The administration of streptomycin, however, gave rapid improvement and final recovery The fourth patient, who was not treated with streptomycin, died
W F Harvey

CHOLERA

ABDOU, S *Susceptibility to Cholera* *Lancet* 1948, June 12, 903-4 [18 refs]

The epidemiology of cholera as regards its vibrio, its incidence and its spread, presents many problems for debate Susceptibility and severity are two outstanding problems and these are the subjects treated by the author Cholera "does not strike all classes with the same severity" One Egyptian village of 1,600 inhabitants presented a good example Many of the inhabitants suffered from multiple infections schistosomiasis, ankylostomiasis, amoebiasis, ascariasis and malaria One family group of 150 persons contrasted markedly with the rest, for it was free from parasitic infections and all of them "in spite of their varied economic status" escaped the infection There were 52 cases of cholera in the village with 25 deaths The deaths were distributed—so far as examination proved it—among those suffering from intestinal schistosomiasis or some other parasitization with or without pellagra Eleven deaths out of 21 were in children and these had not been examined for parasites "Anyone over the age of one year who had diarrhoea and vomiting and died within two days" was considered to have had cholera The author pays attention to the pathways of human infection, the oropharyngeal and the gastro-intestinal, and discusses the bearing of gastric acidity on susceptibility, achlorhydria and hypochlorhydria would remove the barrier to passage of vibrios into the intestine Another puzzling circumstance in this village outbreak was, for a disease with the case-to-case reputation of cholera, that seldom more than one member of any household was attacked with cholera "If the vibrio crosses the stomach barrier, its further fate depends on many factors, of which the intestinal pH is perhaps the one that determines the development of disease or of the carrier state, or the destruction of the vibrio" Vaccination was started five days after notification of cholera, but the author concludes that "a high standard of sanitation seemed to be a better safeguard than immunization"

AMOEBIASIS AND INTESTINAL PROTOZOAL INFECTIONS
CALVO FONSECA, R *La incidencia de la E histolytica en Cuba* Plan pa lograr la uniformidad de los métodos de investigación y técnicas de examen coprológico a usar en las encuestas sobre *E histolytica* en los países Americanos [Incidence of *E histolytica* Infection in Cuba Plan to secure Uniformity of Method in American Countries] *Bol Oficina Sanitaria Panamericana* 1947, Nov-Dec, v 26, Nos 11/12, 943-53 English summary

Records of the incidence of *E histolytica* infection in Cuba have been very contradictory and misleading They have been made in a few, isolated districts and returns have ranged between 1.2 and over 30 per cent Moreover, some observers have classed *histolytica* infections under the general term amoebiasis, not distinguishing this species from *E coli* and *Endolimax nana*

"3. It is suggested that the source of the riboflavin found in the bugs fed on rats deficient in this vitamin is the intracellular symbionts which every bug is known to possess."

PESA CHAVARRIA, A., SÁENZ HERRERA, C., CORDERO, E. & BOLANOS, L. Enfermedad de Weil en Costa Rica. Estudio de un brote epidémico en la ciudad de San José [Weil's Disease in Costa Rica. Study of an Outbreak in San José.] *Bolet. Oficina Sanitaria Panamericana* 1947 Nov-Dec, v. 28, Nos. 11/12, 930-66. English summary.

The outbreak investigated occurred in June-August 1944. Sporadic cases, or small groups of cases, had been observed for several years among children but these had been regarded as cases of catarrhal jaundice. The first patient seen in this outbreak was a child, 5 years of age who suddenly became feverish, and irritable and had loss of appetite, headache, intestinal disturbance, albuminuria and, after 4-5 days, jaundice. Leptospirae were seen in the urine. She was discharged from hospital after being ill for a little more than a fortnight. In rapid succession other cases occurred, in adults as well as children, and altogether 34 cases were recorded. In all but one leptospirae were found in the urine or blood and sera agglutinated *L. interrogans* in dilutions up to 1:5,000 and a few *L. ranicola* up to 1:100 (in one patient 1:200). Rats in the neighbourhood were examined and 31 out of 74 had a blood infection; another 4 per cent showed leptospirae in the urine and 18 per cent in the faeces, 62 per cent positive altogether. Examination of the stomach contents of fleas caught on the rats also revealed leptospirae. It is thought, therefore, that this insect may be a vector of infection. *H. Harold Scott*

LEPROSY

LEPROSY IN INDIA 1948, Jan. v. 20 No. 1 100 pp. Special Issue. All-India Leprosy Conference, Wardha.

This Conference was attended by 74 delegates and a number of politicians. The 100-page report contains little that is new. The first part is taken up with short speeches by politicians from each province and an address by the Director of Health Services Government of India and is followed by abstracts of papers and their discussion; these deal with different sections of the work and the resolutions adopted by the Conference. The main part of the report records either in full or in abstract the papers read, such as mentioned in the earlier part but with no reference to the pages where they are recorded, nor are those of the same subject printed together which is an inconvenience to the reader. No list of papers or index is supplied.

The following summarizes the most important points apart from the 10 important subjects, which are dealt with separately below.

A discussion on planning of anti-leprosy work follows the usual lines: small colonies for 100 patients near their villages are recommended when a near-by medical man is available. The optimum number of colonies for large or remote areas is considered to be 500. In the opinion of the conference, the importance of diet, leprosy control in rural areas, and the importance of dealing with and distributing

Leprosy

Vol 45, No 9]

profession Leprosy surveys are considered to be no longer required except as a preliminary to effective anti-leprosy work. In Orissa, a three years' survey of 1,400,000 persons revealed 25,000 cases, about 4,000 of whom were infective.

A long discussion of social and economic aspects of leprosy included full consideration of sterilization of males by vasectomy to prevent children being born to infective parents. This was thought to have a place, but should be a voluntary procedure. The importance of leprosy in children was once more stressed and special institutions for isolating children living with infected persons were advocated by RAMANUJAM (whose paper in summary was presented by COCHRANE), but others thought it better to send them to live with healthy relatives.

As in the case of all recent leprosy conferences much time was expended on reading papers on and discussing the classification of leprosy cases, much to the confusion of most workers on the subject. It was ultimately resolved that it would be unwise to discard completely the Cairo classification, but it should be suitably modified to bring it into line with recent advances. Other resolutions provided for the appointment of an all-India leprosy officer, for more training for leprosy workers and the admission of leprosy cases to general hospitals, it was agreed that home isolation of children is the cheapest method but is not applicable on a wide scale. Further "immediate steps" should be taken to start colonies and group isolation centres in all seriously affected areas. [It is to be hoped that under national government this may be implemented without further delay as a similar resolution was passed at the Calcutta 1920 Leprosy Conference at the reviewer's suggestion with practically no effect, except in Madras in nearly thirty years.] Further propaganda, research and suitable iteration on political grounds of the title Indian Council of the BRITISH Empire Leprosy Relief Association were also resolved on.

DHARMENDRA Need for Fresh Anti-Leprosy Legislation in India Leprosy in India 1948 Jan, v 20, No 1, 59-63

COCHRANE, R G Legislation in Leprosy Ibid 91-2 Discussion 25-8

The papers and discussion on this difficult subject are of importance. The first speaker pointed out that, except under a recent Madras Act, the legislation is out of date in not distinguishing between infective and uninfected cases and is ineffective in only applying to urban areas. Compulsion leads to hiding and is only necessary under special conditions. Moreover, all Indian institutions are full, so voluntary isolation must be mainly relied on. Fresh legislation is required as a Model Leprosy Act with notification and compulsory powers only as regards infective cases in which lepra bacilli can be demonstrated, provision for isolation of all such cases (a very large order) including those in more highly infected rural areas. In highly endemic areas, legal powers should be mandatory and not only permissive with maintenance of places of isolation for infected cases, and powers for Health officers to examine any cases supposed to be infective. Infective persons should be restricted from the use of public vehicles and from engaging in occupations that may endanger others, and infected paupers rendered liable to arrest and removal. Control of immigration of leprosy patients and regulations regarding measures for effective home isolation should be taken. Leprosy workers should be consulted in the framing of the new Act, which is urgently required for circulation to provincial governments before a final draft is enacted.

The second speaker, Cochrane, with experience of the recent Madras legislation, considered that laws which encourage an atmosphere of fear and drive patients into hiding are bad. The majority of infections are in children and young adolescents and only a minority become infective, and they are not equally

dangerous, so only those most likely to come into close contact with healthy persons need be dealt with. It is impracticable and unnecessary to prevent them from travelling in public conveyances except in the case of prolonged close contact in ship cabins. It is also quite impracticable in India to isolate all infective patients and investigation is required to discover the minimum amount of segregation needed to control the disease so it can only be used in limited areas to meet particular and special circumstances and to prove its efficacy.

After a long and discursive discussion it was resolved that existing legislation should be amended in the light of modern knowledge since present legislative measures are of no practical value.

SMOORS R. D. G. P. Enkele klinische gegevens over een 87 tal leprosiëden. "Biotropisme indirecte 1 pretese der antisyphilitische behandeling, Photosensibilisatieproef op de na lepra. [Clinical Features. Indirect Biotrophism and Photosensitivity Testing in Leprosy] Nederl. Tijdschr. v. Geneesk. 1948, May 29 v. 92 (d) No. 22, 181-197 figs. (8 on 1 pl.) English summary (8 lines)

Many interesting features of leprosy are recorded in this study of 87 leprosy patients, in whom the diagnostic complications of syphilis and skin diseases were increased by avitaminosis and nutritional disturbances acquired in concentration camps. Leprosy manifested itself in the accepted forms of lepromatous and nerve leprosy but the latter showed out only as "hansmales" (tuberculoid) but also as "intermediate" forms. It is evident that when dealing with the signs of leprosy definition of terms is very necessary and that care must be taken over the significance of terms such as tuberculoid, tubercular, syphilitic and leprosy. The leprosy "macula" also may be a raised patch and not the dermatologists' macula.

Among these patients there appeared useful leprosy signs such as madarosis (loss of eyebrows), i.e. leprosy, gynecomastia, claw hand and *ungues dystrophici*. Those doctors who work in leprosy-ridden countries are probably on the look-out for typical and atypical manifestations of leprosy. Two unusual manifestations among many others are described here. The first is cited as a case of indirect leprosy biotrophism. Direct biotrophism is the reaction brought out say in syphilis by a specific provocative dosage; the indirect reaction is that pertaining to some other disease, say a malarial attack which is precipitated by antisyphilitic treatment. In the present instance a 20-year-old patient with primary syphilis, after his ninth injection developed a typical acute leprosy reaction with leonine faces and acid fast bacilli in his nasal mucus. It had evidently been at the same time a case of latent leprosy.

The second case was peculiar: an 18-year-old blonde youth with declared photosensitivity of the skin upon treatment with bergamot oil and exposure to sun. It was a case of nerve leprosy and many of his neurotrophic leprosy skin areas, although devoid of lanugo hair and showing altered pain and temperature sensation, analgesia and thermo-anesthesia, but not touch sensation were immediately reversed by application of bergamot and exposure to the sun. This should have been followed by dermatitis and subsequent darkening of the reaction areas. The leprosy maculae however remained depigmented as vitiliginous leprosy, the areas of analgesia in which, in some cases, were only punctiform.

The lepromin and phorbacaine tests in these leprosy patients followed well known lines.

DHARMENDRA & CHATTERJEE, K R Treatment of Leprosy with the Sulphone Drugs *Leprosy in India* 1948, Jan, v 20, No 1, 71-5 [12 refs]
Discussion 32-4

This trial was carried out on 50 advanced and lepromin negative lepromatous cases in a Calcutta hospital over a period up to 19 months, during the course of treatment blood changes were watched and a diet with increased proteins and vitamin B was given. Promin, diasone and sulphetrone were administered in the usual doses. The first was found to be too toxic, but the last two given orally proved to be more effective than any other treatment, although slow in their action. Simple estimations of haemoglobin only sufficed to enable consequent anaemia to be combated, because its decline runs parallel to that of the red corpuscles and it is not necessary to estimate the concentration of the drugs in the blood except for research purposes. Only a few of the patients failed to tolerate the treatment. Improvement is seen in the form of subsidence in the extent of large infiltrations and nodules and disappearance of small nodules. Leprotic ulcers, including nasal ones, heal quickly and do not recur, and eye conditions improve. Reactions are checked and become less frequent. On the other hand, bacteriological improvement was not marked and in only two cases did smears become negative although in others the numbers of bacilli were generally less. These drugs had no effect on nerve pains and nerve abscesses, and loss of sensation did not show any improvement. Altogether the effects were less than those described by others and these preparations have definite limitations, but the new treatment is considered to be safe, if the precautions already mentioned are taken. Hydnocarpates, therefore, remain the best routine treatment in the generality of cases and especially in many neural ones.

In the discussion which followed, Cochrane repeated his view that the sulphone drugs should be restricted to experimental trials until more experience is acquired, but in his reply Dharmendra said there was no justification for holding back the use of these drugs by general practitioners so long as the necessary simple blood examinations and other necessary precautions were taken. A T ROY advocated giving hydnocarpus oil in a few courses of big doses followed by smaller ones, he considered that this produced the best results.

HELMINTHIASIS

LOVETT-CAMPBELL, A C A Note on Bilharziasis in West African Troops
Trans Roy Soc Trop Med & Hyg 1948, May, v 41, No 6, 821-2, 1 fig

Of 532 military recruits admitted to a hospital in Northern Nigeria in 19 months between 1940 and 1942, 74 had schistosomiasis [this is shown as 18 per cent, but is in fact 13.9 per cent]

S haematobium accounted for 59 cases, *S mansoni* for 11 and a combination of both for four. One of the last named died. Hookworm and ascariid infections were also present in 60 per cent of the infected group and *P falciparum*

malaria in 5 per cent. Haemoglobin varied between 65 and 85 per cent and eosinophilia from 8 to 19 per cent. Red cell counts were never below four million per cmm. Treatment was by means of anthelmaline response to this drug alone was slow so a concluding course of sodium antimony tartrate was given in each case.

The men had been medically examined on enlistment and those infested with schistosomes had been either rejected or treated. It is therefore likely that the present infestations were either those overlooked on enlistment or relapses after inadequate treatment had they been new infestations contracted during manoeuvres a much higher percentage would have been expected.

Contrary to a belief held at the beginning of the war that schistosomiasis caused little physical impairment in recruits, infested men soon broke down under prolonged stress. This was especially noticeable on long marches and a distinctive triad of symptoms was common namely backache in the loins, caecal tenderness and mucoid diarrhoea. Where backache predominated vesical lesions tending to encroach on ureteral orifices were seen on cystoscopy. Caecal tenderness indicating large bowel involvement was common in *haematolyticus* as well as *mansoni* infestations and one soldier had gross *haematolyticus* lesions in the appendix.

In an endemic area in the Sokoto Province 57 per cent. of 35 appendicectomies revealed schistosome infestation. Appendicectomy is usually indicated in schistosomiasis where caecal tenderness remains after specific drug therapy or radiography shows imperfect filling or delayed emptying of a retrocaecal appendix.

MEESER, C. V., ROSS, W. F. & BLAIR, D. M. The Diagnosis of Rectal Schistosomiasis. *J. Trop. Med. & Hyg.* 1948, May v 51 No. 5 91-4

A diagnosis of rectal schistosomiasis is usually based on the recovery of ova of the worms from the stools. In S. Rhodesia, where the severer dysenteric form of the disease is rarely seen even serial stool examinations may reveal but an occasional egg. Here in many cases giving a positive intradermal test with a cercarial antigen, eggs cannot be found in the stools but postmortem infection of internal organs can be demonstrated by a potassium hydroxide digestion technique in these cases.

In 1921 FILLIBORN (*this Bulletin* 1923 v 20 19) described a concentration technique for the recovery of schistosome ova from stools and the recognition of their presence by hatching. A modification of this method has been employed in S. Rhodesia. In 1943, OTTOLINA and STENCIO (*ibid.* 1944 v 41 845) examined the diagnostic results yielded by liver puncture and by rectal biopsy in schistosomiasis. GELFAID (1948 in the Press) is stated to have found rectal biopsy a successful method of diagnosis of schistosomiasis in S. Rhodesia. HERNANDEZ MORALES and MALDONADO (1946) (*ibid.* 1947 v 44 300) found the biopsy method to give 100 per cent positive result as compared with a 40 per cent result yielded by a stool concentration technique. KNABITZ and SALAN ET AL. (1930) (*ibid.* 1930 v 27 983) compared the results obtained from direct stool examination from a stool flotation technique and from rectal swabs. Of these the rectal swab method gave the higher number of positive results in rectal schistosomiasis. WALLER (1947) (*ibid.* 1947 v 44 509) designed grooved rectal swabs and by this method detected 61 per cent of cases, while an acid-Trisodium SE-ether faecal concentration technique in Luanda revealed 78 per cent positives.

The authors examined 50 unselected Africans in the Salisbury Native Hospital for rectal schistosomiasis using (1) their cercarial antigen intradermal

test, (2) rectal biopsy, and (3) a Weller's three-grooved scraper as diagnostic procedures. Of these, 41 gave positive intradermal tests, 27 gave positive rectal biopsies, and only 2 were found positive by Weller's scraper technique, 4 were negative as judged by all these tests. A further series of 17 cases was examined by biopsy and by Weller's scraper, 14 of these were shown to be positive by biopsy, but only one with the scraper, this latter was a case not revealed by biopsy. Ten other cases of schistosomiasis with *S. mansoni* ova in the stools were examined by Weller's technique, and from only one of these did the scraper recover eggs.

Weller's scraper therefore proved an unsatisfactory instrument for the detection of rectal schistosomiasis as encountered in S Rhodesia. The reason for Weller's own success in its use may be attributable to the fact that *S. mansoni* infestations are much heavier in Egypt and in the Caribbean area than in S Rhodesia, where diarrhoea, with the passage of blood and mucus, rarely results from them. Furthermore the scraper takes material only from the lowest 9 cm of the bowel, while biopsy yields material from a level about 15 cm up the bowel.

In 5 cases with negative intradermal tests biopsy yielded eggs. Eggs obtained by biopsy are not always viable, in many cases they were seen to be dead and degenerate. Their presence, therefore, while it constitutes residual evidence of an infection, does not necessarily indicate a need for specific treatment. Old-standing cases of rectal schistosomiasis may be self-cured, and specific treatment is necessary only when the eggs are demonstrably viable.

In S Rhodesia, cases of infestation with worms producing terminal-spined ova far outnumber those harbouring *S. mansoni*. The rectal biopsy technique revealed a much higher incidence of terminal-spined egg infestation than did stool examination, Weller's scraper usually failed to reveal intestinal infestations with terminal-spined eggs. It would seem that terminal-spined eggs have difficulty in escaping from the gut wall into the intestinal lumen.

MAKAR Bey, N Two Interesting Cases of Bilharzial Papilloma and Epithelioma
J Roy Egyptian Med Ass 1948, Mar, v 31, No 3, 217-21, 1 coloured fig, 2 photos & 4 microphotos on 6 pls

In the first case, the patient, an Egyptian male of 25, suffered from a large ulcerating cauliflower-like mass which protruded from the anus. He had a past history of intestinal and urinary bilharziasis which had been treated repeatedly. dead schistosome ova were found in the urine and stools, and X-rays showed "bilharziasis of the bladder". A course of tartar emetic was given and the growth was removed later by diathermy in two sittings. The pathological report revealed that the growth showed "the typical structure of bilharzial polyposis". It contained many living and dead ova, but no malignant changes were seen. The author points out that such advanced conditions are not commonly seen nowadays, and he is of the opinion that neither tartar emetic nor any of its substitutes affect the fully developed bilharzial lesion, possibly because of fibrosis obstructing the vascular channels. The advantages of the form of operation employed are discussed.

The second case was that of an Egyptian male of 40, complaining of a warty mass on the inner aspect of the right thigh, below the crease of the groin. It had begun in the form of nodules in the skin three years before. There was a history of haematuria occurring 2 or 3 years before the skin nodules developed. *S. haematobium* ova were present in the urine.

After a course of tartar emetic had been given the mass was excised. Schistosome ova were found in the dermal papillae and superficial currum. Parts of an ulcerated area of the growth were typically epitheliomatous. The patient received radiotherapy and was apparently cured when he left hospital.

The author points to the rarity both of schistosomal leucos in such a site and of the appearance of epitheliomatous changes in them where the skin is not exposed to such irritants as occur when the lesions exist at mucocutaneous outlets.

Because of this rarity and the initial difficulty in diagnosis, the case was at first thought to be one of leishmaniasis with superimposed epitheliomatous changes.

GELFAND M. The Prognosis in Schistosomiasis. *J Trop Med & Hyg* 1948 June v 51 No 6 117-19 [23 refs]

The gravity of schistosomiasis as a cause of disablement and of death among Africans in S. Rhodesia is examined. Digestion of the rectum and of the bladder obtained post mortem from 300 adult natives of Mashonaland showed 94 per cent. to be infected with schistosome ova.

Cirrhosis of the liver occurs in 8 per cent. of Africans, and primary liver carcinoma in 1 per cent. of them although first ascribed to schistosome infection a similar incidence of these conditions has been reported from schistosome-free areas. The author does not accept schistosomiasis as a cause of liver cirrhosis and believes this to be due to some other factor such as protein deficiency. The liver changes in schistosomiasis are localized around the eggs, there is no alteration in the main hepatic structure or evidence of liver

Almost half of the schistosomiasis patients had ova in the lungs but pulmonary and dilatation of the right heart due to pulmonary arteriosclerosis, Werz's syndrome and pneumonia and other pulmonary disorders attributable to infection were not found at the 300 post mortem examinations, although schistosome infection of the appendix is common and chronic appendicitis rare in the Bantu.

Stricture of the ureters with back pressure, hydronephrosis is much less frequent than dilatation of the ureters. hydronephrosis may be associated with this dilatation owing to impairment of the peristaltic function of the ureter because of its thickening. the back pressure may be augmented by reflux of the urine from the bladder through the incompetent ureteric orifice. Eighty-three (33 per cent.) of 250 cases had gross lesions of the ureters, and of these about 77 per cent. consisted of dilatation alone, only 3 per cent. showed stenosis. Fifteen per cent. of the 83 (5 per cent. of the total cases) had hydronephrosis which was usually associated with ureteral dilatation. Only 1 per cent. was the hydronephrosis responsible for death. Nevertheless, 60 per cent. of those with lesions in the bladder have lesions in the ureters and half of these develop either dilatation or stricture of the ureters; a percentage of these suffer from hydronephrosis which will in some cases ultimately cause death.

Acute inflammatory infections of the urinary tract due to schistosomes are not clinically common and rarely do they cause death. Stone formation is extremely rarely due to the schistosomes per se. vesical carcinoma is relatively uncommon, occurring in only one quarter as many cases as primary carcinoma of the liver. Carcinoma of the bladder indeed is less common than in Europeans, in spite of the high incidence of vesical schistosomiasis in the Bantu. The effect of schistosome infection on other organs is problematical. The author

considers that schistosomiasis is not as serious a disease as is claimed in the literature, and that its true gravity is primarily due to its effect on the ureters

- A R D Adams

[Much of this paper deals with schistosomiasis without distinction of species, although the author's observations on lesions of the urinary tract refer specifically to *S haematobium* infections, he does not always indicate which species is concerned in other lesions. He does, however, state that his findings do not bear out the current belief that *S mansoni* has a greater predilection for the liver, and in his own experience he found *S haematobium* ova in the liver in just under 50 per cent of the cases, but those of *S mansoni* in just over 23 per cent. He also quotes SHAW and GHAREEB (this *Bulletin*, 1938, v 35, 665) who conclude that Ayerza's disease may result from either species. In the section dealing with appendicitis, no indication is given of the species of schistosome involved. It is of some importance, in papers dealing with schistosomiasis, that whenever possible the species concerned should be indicated so that subsequent references in the literature may be clearly related to the particular aetiological form of the disease. Ed]

HALAWANI, A, WATSON, J M, NOR EL-DIN, G, HAFEZ, A & DAWOOD, M.
Miracil D a New Chemotherapeutic Agent for Bilharziasis *J Roy. Egyptian Med Ass* 1948, Mar, v 31, No 3, 272-84

Miracil is a new compound, 1 methyl-4-beta-diethyl-amino-ethyl amino-thioxanthone HCl [this *Bulletin*, 1948, v 45, 526]

The compound was given orally to 16 patients infected with *S haematobium*, who were subsequently examined at weekly intervals for 2½ months. Ten received total doses of 2 to 5 gm during 5 to 10 days, apart from one very light infection, none of these was cured. Three patients were given 7.5 gm during 8 to 10 days, two were cured and one relapsed. The concentrations of miracil in the blood mostly ranged from 0.12 to 0.37 mgm per 100 ml. In ten cases the drug caused slight increases in the systolic blood pressure and in the pulse rate. Among the symptoms reported by the patients were — giddiness (10 patients), vertigo (1), weakness and inertia (2), headache (2), epigastric pain (2), colic (2). The patient with vertigo suffered severe and repeated attacks of giddiness beginning 7 days after taking the last of 3 doses of 0.4 gm each, given at intervals of two days, these attacks lasted for 9 days and then diminished in intensity. (This patient also showed a rise in blood urea from 24 to 35 mgm per 100 ml). Giddiness also required discontinuance of the treatment in two other patients receiving 10-12 mgm per kgm daily (i.e. 0.5 gm twice daily for several days). Muscular twitching occurred in a few patients and excessive sweating in others. The skin was stained yellow. One patient weighing 45 kgm who had received 1 gm daily for 7 days developed an erythematous rash over the body and face, this disappeared after a few days. Apart from the case of the one patient mentioned above, there was no change detected in kidney function, in hepatic function, or in the blood. In three cases, temporary changes were observed in the heart. Three of the patients treated also suffered from *S mansoni* dysentery, two were not cured, one (apparently) was sterilized temporarily but relapsed. In cases which responded, the excreta became negative 7-10 days after the end of treatment. Apparently miracil does not have a direct action on the eggs. Three additional patients were each given 1 gm daily for 7 days, and viable ova had completely disappeared within three weeks of the end of treatment.

It is concluded that the effective dose of miracil is not less than 18-20 mgm per kgm daily for 7-8 days, and that the blood concentration must reach 0.3 mgm per 100 ml

F Hawking

HAWKING F & ROSS W F Miracil D Its Toxicology Absorption, and Excretion in Animals and Human Volunteers. *Brit. J. Pharmacol. & Chemother.* 1948 June v 3 No. 2, 167-73 "figs."

Miracil D synthesized in Germany is the hydrochloride of 1-methyl-4- β -diethylaminoethylaminothioxanthone

and showed promise against infections of *Schistosoma mansoni* in mice. The present authors have studied its effects and blood levels in mice, rabbits, monkeys and human volunteers. It has an irritant action on tissues giving rise to inflammation and necrosis at the site of injection and it causes slight spasm of intestinal muscle. It is more toxic when given intravenously and may produce venous thrombosis. Oral dosage proved most satisfactory. Details of dosage are recorded. In man 0.2 gm. repeated daily was tolerated. The method of LATNER *et al.* [this *Bullet.* 1948, v 45, 86] was used for estimation. When the drug was given orally in a single dose absorption was rapid and the blood level attained in some animal experiments was constant for at least 21 hours, but was not always proportional to dosage. In man the concentration in leucocytes, plasma and red cells was in the order given. The drug was present in most tissues of the body. About 7 per cent. of an ingested dose was excreted in urine and less in faeces, and the drug disappeared from these excretions in 1 to 3 days after treatment. About 90 per cent. appeared to be degraded in the body with consequent little tendency for accumulation. In animals, overdose caused pathological changes in liver and kidney, while in man nausea, prostration, insomnia and yellow discoloration of skin and sclerotics were encountered.

J. D. FAISON

MARILL, F. G. La bilharziose vésicale en Algérie. Programme de prophylaxie [Urinary Schistosomiasis in Algeria: the Programme for Prevention.] *Cahiers M.H.U. sous l'auspice Algiers* 1947 Nov. v 2, No. 14 677-91

In January 1947 a focus of infection with *Schistosoma haematol.* was found at Fondouk, and known foci exist at Djinet and Saint-Vincent-de-la-Oghlona. The Fondouk focus is only 84 kilometres from Algiers.

Schistosomiasis may be introduced into Algeria from Southern Tunisia, Morocco and especially from south of the Great Atlas mountains, but there are now there several established foci in the country and in many other places *Bulinus* snails are found. The author mentions *Bulinus truncatus* (and *B. contortus*, *B. dybowskii* and *B. nana* which others regard as synonyms of the first), *B. symoudianus*, *B. brachius*, *B. trondelsi* and *B. marinus*. He makes the point that if snail hosts are present in collections of water prolonged contact with carriers of the infection is necessary before a focus is started. Irrigation canals are suitable for snails and for human contact and the disease is largely associated with irrigation systems. The smaller canals are most frequently infested. In Saint-Vincent the number of snails has diminished as a result of deliberate periodic drying of the canals but this is probably not enough to account entirely for the diminution that has taken place. Other infections have probably affected this comparatively new colony of snails, but they are not understood. Cemented canals in that area contain only *Melanopsis* with 1 containing chiefly *Bulinus* and only rarely other genera.

Helminthiasis

Vol 45, No 9]

The author discusses control The number of foci of snail hosts in Algeria is so large that in practice they cannot be dealt with, but the foci connected with irrigation can be controlled, and on these all efforts should be expended. Patients should, of course, be treated, especially soldiers drafted into these areas from Morocco and elsewhere, but examination by cystoscopy has shown that 80 per cent of African soldiers may be affected, and the trouble and expense of a complete treatment programme would be so great that it is doubtful if it could be carried through. Workmen entering from Southern Morocco should be examined at the frontier, but frontier posts are very easily avoided. Nevertheless, it is possible to control these men so that they are not permitted to stay or work unless certified as free from schistosomiasis.

For control of snails it is necessary that engineers and others engaged in irrigation work should constantly bear in mind that snail elimination is an essential part of the work. In each irrigation system there should be a full-time sanitary section directed by an expert chief. Earth canals should be cemented. Canals should be dried periodically—at Saint Aimé, experience has shown that *Bulmus* snails cannot withstand 6 hours of summer sunshine in a dried cement canal, but shade along the edges prevents this lethal action. Earth canals give much more protection to the snails. Certain sections of canal, and the larger canals, can rarely be dried, but the author suggests that these larger channels might be doubled and therefore used alternately, or provided with sluice-gates at intervals so that sections may be dried in turn.

Copper salts may also be used, but if a copper compound were introduced to a strength of 1 in 200,000, which is usually required for *Bulmus*, there would be needed, for the Saint-Aimé system alone, some 650 tons each year. If, however, copper salts are reserved for parts of the system permanently under water—siphon pits, small reaches, pools, etc.—which form the reservoirs of snails, they may be most useful.

Such measures are useful for the control of schistosomiasis, but they are also of considerable value for the control of malaria in that they entail careful watch on permanent collections of water. Each irrigation system, however, presents its own peculiar problems.

Charles Wilcocks

KOURÍ, P. Diagnostico, epidemiologia y profilaxis de la Fascioliasis hepatica humana en Cuba. **Síndrome eosinofílico febril [Diagnosis, Epidemiology and Prophylaxis of Human Fascioliasis in Cuba]** Kuba Habana 1948, Mar, v 4, No 3, 63-7 [48 refs]

Clinical diagnosis of infestation by *Fasciola hepatica* is not easy, the main symptoms are those of cholangitis, cholecystitis and hepatic colic which may, of course, be due to several other causes. Finding of the ova in the faeces is conclusive but not infrequently the diagnosis has been made when an operator is in progress, or even at autopsy. Eosinophilia, especially if of an epidemic character and accompanied by prolonged fever and leucocytosis, perhaps with shivering and a painful enlarged liver, is a helpful indication. Apart from direct faecal examination and the persistent eosinophilia, complement fixation, precipitin- and intradermo-reactions with extracts of the trematode may be tried, but these are not yet established procedures. The therapeutic test—clearing up of symptoms on administration of emetine is not of much value, an amoebic hepatitis would be cured by the same treatment.

From the epidemiological point of view, the infestation of cattle is all important. One record of 549 cattle slaughtered at the municipal abattoir of Pinar del Rio gave 61.9 per cent with *F. hepatica* in the bile-ducts. Generally speaking [no figures are given] "human fascioliasis is more common in the white than in the negro, more in the middle and upper classes of society

O'NEAL, RUTH & MAGATH, T. B. Trichostrongylus Infection of Human Beings: Report of Three Cases. *Proc. Staff Meetings Mayo Clinic* 1947 May 14 v. 22, No. 10 193-7 2 figs.

Trichostrongylus infections were diagnosed by finding eggs in the stools of two boys aged 5 and 7 respectively and a man of 78 years. The two boys had lived in the Belgian Congo and French Equatorial Africa from an early age and the adult had spent 13 years in Korea.

A good series of photomicrographs illustrates the progressive development of the eggs up to the embryonated stage. The eggs measured from 7.6 to 8.6 μ in length by 4.4 to 4.7 μ in width. J. J. C. Buckley

BRUAL, V. L. über die Wirkung des ReinsBenzins auf die Darmparasiten und seine Folgen. [The Effect of Pure Benzene on Intestinal Parasites.] *Schweiz. med. Woch.* 1948 June 12, v. 78, No. 23, 571-2.

Petroleum and benzene have been used for some years in Anatolia in the treatment of intestinal parasites, particularly by veterinarians for treating ascaridiasis and strongyloidiasis in horses and the author has undertaken a study to determine the uses of benzene and whether its exhibition has any disadvantages and sequelae. The benzene on the market is not pure—it is mixed with 15 per cent methyl alcohol and lead and is therefore dangerous. By distillation a pure product has been obtained. Starting with 0.3-0.8 cc. for each year of life as a minimal dose he obtained no result so he gradually increased it to 20 cc. for a child of 2-5 years, 30 cc. for those between 6 and 14 years and 60 cc. for an adult. Burning sensation in the stomach and anus was observed by giving the drug emulsified in syrup and gum arabic with a little oil of pepper mint. It is given in the morning, before food is taken, and is followed by a purge of sodium sulphate. After 2-3 hours light food may be given such as soup, milk pap, potato consommé, fruit juice etc.

In this way the author has treated 57 cases of ascaridiasis, 48 of teniasis, 45 of oxyuriasis, 5 of ankylostomiasis and 14 of mixed infestations. Relapses have been observed in 7, 4, 8, 1 and 0 respectively. Symptoms of intoxication are few and slight, in fact almost negligible—they included a tendency to drowsiness, some giddiness and nausea, rarely vomiting and burn sensations in the stomach and at the anus. In animal experiments as much as 8 gm. per kilo was given to dogs without producing any toxic symptoms.

H. Harold Scott

LACE, C. Bancroftian Filariasis. Biological Mechanisms that underlie its Periodicity and other of its Clinical Manifestations. *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948 May 41 v. 4 717-84 7 charts & 58 figs. on 23 pls. (Numerous refs.)

Opinions as to the causes of macrofilarial periodicity have so far been mainly based on theory. Some authors, like PUTZIG and HOLMES (this *Bulletin* v. 1939 v. 38 149) despairing of any satisfactory planar explanation of the matter as of little importance as well as a fact but by others it is regarded as embodying a vital principle. It is claimed by LACE that speculation on this subject has so far been based insufficiently on histological studies but these have now been made possible as a result of some 200 filarial sections impregnated to him by the late Professor F. W. O'CONNOR. Reviewing the histological aspect of the mechanism of periodicity MEARS (1881) held that the parturition of female filariae was continuous and that the embryos remained in the lymphatic system for 12 to 24 hours when they entered the bloodstream they were destroyed during the daylight hours. MEARS (1881) on the other hand

suggested that reproduction was continuous, but that the embryos were filtered out in the lungs during the daytime. He thought that the object of Nature in making this creature so prolific was, to provide as many chances as possible for the continuance of the species, and so he found it difficult to understand why animalcules which can live many days *outside* the body of their host should die after so short a life *within* it.

From a reconsideration of Manson's data on the numbers of microfilariae present at the same hours in the blood and in lymph measured by chyle deposited in urine, it appeared that a periodicity in the lymphatics was emphatically present, but according to Lane, this differed from that in the blood by observing a morning peak. At first it appeared to Manson that filarial disease, such as lymph scrotum, could be brought about by the activities of one parent worm, but Myers recorded that the human host could harbour many at the same time. From O'Connor's serial sections it has been confirmed that 80 worms (either killed by the fixative or already defunct) could be found in a set of inguinal lymph glands in one case, and over 30 in a second. Therefore periodic parturition by one single worm cannot be held to account for the cyclical appearance of embryos in the peripheral blood.

Since the acceptance of ASCHOFF's conception of the function of the reticulo-endothelial system as a destructive and defensive mechanism, and by taking this into account, the long life of the microfilaria outside the body can no longer be taken as evidence that an equally long one can be expected within the human host. Nor could Manson visualize that, though a great mortality of the microfilariae would ill serve the parasite, it would ultimately benefit the human host. Thirdly Manson did not appreciate the fact that the lymph flow does not cease at death, but that at *post mortem* the flow of lymph may be prolonged or even increased, so that after death it may have borne microfilariae into unexpected situations. Therefore his findings that microfilariae harbour by day in the lungs and the larger systemic arteries and thereby produce periodicity by disappearance from the skin blood can no longer be accepted as correct [but see reviewer's comment, below]. It was in 1929 that Lane, on the arguments stated above, formulated his cyclical parturition theory. He found himself incapable of conceiving a possible daytime withdrawal of microfilariae from the cutaneous to the deep capillaries. If this was the case then there must be either a periodic contraction of these capillaries, or a periodic posturing of microfilariae within them during the day. In the case of the nocturnal *W. bancrofti* these forces would have to come into action by day only, by night in the case of *L. loa*, and at no time in the cases of *A. perstans* and the non-periodic Pacific variety of *W. bancrofti*. What would happen in a double infection of two species of periodic microfilariae under these conditions beggars imagination.

As is well known, Lane's theory postulates that periodicity must be due to simultaneous microfilarial parturition once in 24 hours by the females, and the periodic destruction of these newly-born embryos within the organs each and every day. At this point the story digresses to discuss the pertinent question of the mechanism underlying the regular rhythms of inflammatory attacks in Bancroftian filariasis. A possible route by which microfilariae may migrate from the vicinity of the parent worm in the lumen of the lymphatic through its walls to neighbouring small blood vessels, on their way to the general circulation, has now been demonstrated, though it is not claimed as the normal method. It has been believed that death and destruction of microfilariae in process of transit cause attacks of acute inflammation. Thus O'Connor thought that in sections of a lympho-varicocele he had obtained visual evidence of this transit. The larval sheaths (as in other nematode larvae) are separated, but enclosing cuticles which are cast at the last ecdysis, and therefore should be

discarded in this transit. During the development of the larva in the intermediate host it escapes from the sheath by fixing the anterior end of the sheath against an obstacle and by boring through it towards that obstacle. Normally this is the midgut of the mosquito but this thigmotactic urge, it is claimed, is present during its sojourn in the human definitive host and is revealed by the actual presence of discarded sheaths in the viscera (illustrated by two microphotographs in the text, the interpretation of which is open to some doubt). On the other hand, penetration of tissue without loss of sheath is possible as has been demonstrated by HAWSON in *Leishmanoides pullerossi* of the cotton rat.

Mammalian striped muscle is exceptionally rich in lymphatics and is a possible route (lymphatic escalator) for microfilariae from the pleural lymph sac along the rich plexus of the diaphragm towards the great veins. On the other hand, active penetration of *W. bancrofti* from lymph to blood must be a rare event because otherwise sheathless microfilariae would commonly be found in blood preparations.

No evidence however has been forthcoming that acute inflammatory attacks are connected with massive birth of microfilariae to their subsequent burrowing through the tissues or to their death in these situations. On the other hand Lane believes that a superadded bacterial infection is much more likely to be responsible for acute lymphangitis. For the species to survive it is obvious that the numbers of circulating microfilariae must be kept up by new births in order to make good the wastage. Should these births take place periodically at the time of, and be the cause of, fever and inflammation, then a number must reach the bloodstream, and therefore an increase in the number of circulating microfilariae should be expected, but just the reverse is the case.

Some space is devoted to the fifth theory [KILLER, this Bulletin 1909, Vol. 33]. This assumes a more or less continuous parturition, and the course of periodicity is ascribed to special siting of parturient female worms, to gravity, and to periodic flow of chyle but there is no evidence that any of these factors is operative.

YOKOGAWA's theory (Trans. Roy Soc Trop Med & Hyg 1909 v. 33 363) is even more unlikely. He suggested that the periodicity of microfilariae is chiefly controlled by the diurnal and nocturnal alterations of the physiological functions of the reticulo-endothelium. There is no proof whatsoever that such an intrinsic variation of activity of this system is operative.

Evidence is now offered that in periodic Bancroftian infection two opposing forces operate: (1) synchronized peristaltic parturition and (2) local macrophage activity in the lymphatics and lungs, which brings about complete or partial destruction of the microfilariae.

The points to be established should be that: (1) Periodicity was established at the time the specimens were procured. (2) The worms studied had been killed at the time the tissue was fixed. (3) All the female filariae were in the same stage of parturition. (4) The uterine stat corresponded to a synchronized periodic emptying. (5) The phases of microfilarial blood take were in accord with the differences in the uterine content.

In order to give effect to his findings a detailed description is given by the author of the tubular genital tract of the female *W. bancrofti* special attention being directed to the vaginal pouch (COSMOLD) a study has been made of the worm in tissues when killed by fixative.

From the detailed consideration of the changes observed in the uterine contents, the author concludes that there is a stage in which the uterine stems and the anterior branches are filled with outstretched embryos lying for the most part parallel to the uterine axis. When uterine peristalsis sets in, these embryonic forms are expelled and their place is taken by upspringing young developing from eggs. The appearances are those of a process of expulsive

emptying parturition, followed by uterine refilling from the ovaries. Pre-microfilarial young are commonly found free in the tissues of the host. This observation was originally used by Manson as the basis of his theory of lymph stasis. But in O'Connor's material these forms were commonly found in lymphatic glands, together with normal microfilariae. The evidence is that many young are born while still coiled within the egg membrane and that they may subsequently rupture and escape from it.

When the microfilariae are found in numbers in by-passing lymph capillaries or in lymph glands, their situation is such as would be caused by a process of expulsive emptying parturition. The main factor in ascertaining from microscopic sections the level to which parturition may empty the uterus is the observation that at any level all the contained microfilariae are at much the same stage of development, but do these synchronized emptying parturitions cause the rise of the microfilarial blood tide? This is answered by the following facts—(1) The tides were present when the specimen was obtained, (2) blood obtained by skin-prick was found enough to establish periodicity, and (3) the parturition of the worm took place at an hour reasonably related to that at which the microfilarial blood tide rose. In lymph glands removed between 13 45 and 14 28 hours [1 45 and 2 28 p.m.], O'Connor found that the uterine stems of the inhabiting filariae were either empty or contained eggs only. In necropsy material, that obtained from persons dying about midnight was particularly helpful. Out of six autopsies in which these conditions were recorded, satisfactory findings were obtained in two only. Nevertheless the findings are stated to be such as would occur if synchronized parturitions expelled a swarm of microfilariae into the lymphstream at such a time as would cast them into the blood during the normal period of the microfilarial tide.

Whatever may be the mechanism underlying periodicity, some stimulus must surely attract the microfilariae into the skin blood at night. This synchronizing stimulus remains unknown. Possibly it may be through the male bringing about coitus and impregnation at a certain hour, or through the female by exciting parturition at a certain hour and thus leaving the uterus empty. The stimulus comes into being once in 24 hours, but produces a response in parasites only when they are ready for it. In the periodic Bancroftian filariasis all female adults are ready for it every night, but here again difficulty arises when stipulating what happens for the non-periodic form, for *A. perstans* and for *L. loa*. The author discusses at length the larvicidal mechanisms which interfere with the rise of the microfilarial tide. It is well known that microfilariae, though born, may not reach the blood. Reasons are given against the belief that embolisms of still-coiled embryos can effectively dam the lymph current through a lymphatic gland, but probably the microfilariae are held back, imprisoned and destroyed by active proliferation of the cells of the macrophage system. By these means the lymph current is slowed down and the microfilariae held where these cells are most numerous. The end result of these larvicidal mechanisms is to produce ever-increasing lymph stasis and such clinical results as hydrocele and elephantiasis. These effects arise from two interacting factors—excessive extracellular lymph protein, and fibroblastic activity. The fibrous formation that they induce round the lymphatic tract contracts and interferes with the further free flow of lymph through it.

There is an analogy between the effects of raised blood pressure and lymph pressure. Vessels become dilated and where they have muscular walls these are thinned or thickened. The earliest evidence traced for this dilatation goes back to Manson's observation of skin vesicles that, when ruptured or pricked, discharged microfilariae. The accompaniment of elephantiasis is presumably due to an increase of extracellular protein in the lymph, brought about by

discarded in this transit. During the development of the larva in the inter-mollate host it escapes from the sheath by fixing the anterior end of the sheath against an obstacle and by boring through it towards that obstacle. Normally this is the mudgut of the mosquito but thus thigmotactic urge it is clumped, is present during its sojourn in the human definite host, and is revealed by the actual presence of discarded sheaths in the viscera (illustrated by two microphotographs in the text the interpretation of which is open to some doubt). On the other hand, penetration of tissue without loss of sheath is possible as has been demonstrated by HAKKIOO in *Leishmaniasis* *pattersoni* of the cotton rat.

Mammalian striped muscle is exceptionally rich in lymphatics and is a possible route (lymphatic escalator) for microfilariae from the pleural lymph sac above, the rich plexus of the diaphragm towards the great veins. On the other hand, active penetration of *W. bancrofti* from lymph to blood must be a rare event because otherwise sheathless microfilariae would commonly be found in blood preparations.

No evidence however has been forthcoming that acute inflammatory attacks are connected with massive birth of microfilariae, to their subsequent burrowing through the tissues or to their death in these situations. On the other hand Lane believes that a superadded bacterial infection is much more likely to be responsible for acute lymphangitis. For the species to survive it is obvious that the numbers of circulating microfilariae must be kept up by new births in order to make good the wastage. Should these births take place periodically at the time of and be the cause of, fever and inflammation then a number must reach the bloodstream, and therefore an increase in the number of circulating microfilariae should be expected, but just the reverse is the case.

Some space is devoted to the fifth theory [HALL, this Bulletin 1939 v 3d, 329]. This assumes a more or less continuous parturition and the course of periodicity is ascribed to special siting of parturient female worms to graze, and to periodic flow of chyle but there is no evidence that any of these factors is operative.

YOKOGAWA theory (*J. nat. Roy Soc Trop Med & Hyg* 1939 v 33 380) is even more unlikely. He suggested that the periodicity of microfilariae is chiefly controlled by the diurnal and nocturnal alterations of the physiological functions of the reticulo-endothelium. There is no proof whatsoever that such an intrinsic variation of activity of this system is operative.

Evidence is now offered that in periodic Bancroftian infection two opposing forces operate: (1) unsynchronized peristaltic parturition and (2) local macrophage activity in the lymphatics and lungs, which brings about complete or partial destruction of the microfilariae.

The points to be established should be that: (1) Periodicity was established at the time the specimens were procured. (2) The worms studied had been killed at the time the tissue was fixed. (3) All the female filariae were in the same stage of parturition. (4) The uterine state corresponded to a synchronized periodic emptying. (5) The phases of microfilarial blood tide were in accord with the differences in the uterine contents.

In order to collect his findings, a detailed description is given by the author of the tubular genital tract of the female *W. bancrofti* special attention being directed to the apical pouch (COMBOD) a study has been made of the worm in tissues when killed by fixative.

From the detailed consideration of the changes observed in the uterine contents, the author concludes that there is a stage in which the uterine stems and the anterior branches are filled with outstretched embryos lying for the most part parallel to the uterine axis. When uterine peristalsis sets in, these embryonic forms are expelled and their place is taken by upsurging young developing from eggs. The appearances are those of a process of expulsion.

determined. Such rats are superior for chemotherapeutic studies and for studies on immunity to wild caught rats with infections of various numbers of worms of mixed ages. Further improvement along this line is needed, however, and to indicate possible lines of procedure the factors in the variability observed in these experiments are analyzed."

PEEL, E & CHARDOME, M. Note complémentaire sur des filarides de chimpanzés *Pan paniscus* et *Pan satyrus* au Congo Belge [An Additional Note on the Filarial Worms of the Chimpanzees, *Pan paniscus* and *Pan satyrus*] *Ann Soc Belge de Méd Trop* 1947, June 30, v 27, No 2, 241-50, 8 pls

The previous discovery by PEEL & CHARDOME [this *Bulletin*, 1947, v 44, 339] of the adult female *Dipetalonema streptocerca* in chimpanzees, is now amplified by a description of the male adult. In addition they have found and identified the adult forms of *Mf rodhaini* Peel & Chardome, 1946, and assign them also to the genus *Dipetalonema*.

Three male *D streptocerca* were collected from the subcutaneous connective tissue of two chimpanzees, *Pan troglodytes schweinfurthi*. They measured 17.5 to 18.1 mm long with a maximum diameter of 46.66 μ . There are three pairs of pre-anal and two pairs of post-anal papillae and a sixth pair 26.66 μ from the caudal extremity, which is described as terminating in two cuticular prolongations. [This description is incompatible with the figures illustrating the ventral and lateral views of the male tail. The two figures are also incompatible with each other.] The unequal spicules average 338.8 μ and 117.4 μ long respectively, and there is a small gubernaculum.

Three female and one male *D rodhaini* were collected from the subcutaneous connective tissue of *Pan troglodytes schweinfurthi*. The male is 19.9 mm long with a maximum width of 53.32 μ . There are two pairs of pre-anal and two pairs of post-anal papillae, and a single pair situated 6.66 μ distant from the latter. The diameter of the single pair of papillae is twice that of the anal papillae. [This makes a total of five pairs of papillae but in the drawing there appears to be a sixth pair between these and the tip of the tail.] The unequal spicules are respectively 366.63 μ and 143.31 μ long. The average length of the female worms is 25.216 mm and the maximum width 83.3 to 86.6 μ . The genital opening averages 502.15 μ from the anterior extremity.

A general account with bibliography

GAYTON, J. L. BELLIS, M. & McCLENNAN, W. H. A Survey of Pinworm Infection in an Elementary School *Canadian J Pub Health* 1948 May, v 39, No 5 200-202

The public health nurse in an area in South Vancouver received repeated reports from mothers concerning minor symptoms in their children attributed to pinworms (*Enterobius vermicularis*). The authors therefore examined 145 of the 160 children in the local village elementary school. Examination was made by means of the Graham swab (three inches of "Scotch tape" held sticky side outwards over the end of an applicator). The swab was then dipped in dilute iodine solution and applied to a microscopic slide for examination.

Of a total of 5144 slides 982 (or 19.1 per cent) were positive. Where more than 100 slides were examined in a village the incidence varied from 13 to 25.6 per cent.

The blood of children under 5 years of age was not examined. In the succeeding quinquennial periods the incidence of positive slides rose regularly from 5.2 per cent. (age 5-9) to 43 per cent. (age 50-54) and then irregularly up to 50 per cent. (age 75-100). The average number of worms "per slide" showed a steady rise up to the 50-54 age group (30.7) but after this tended to fall and was 11.1 in the highest age group.

The rate for microfilariae among men was almost double that of women in all age groups above the age of 20 years.

Elephantiasis was not observed in any person less than 30 years of age. Of 1,575 persons over the age of 30 years from whom blood slides were taken, 61 (or 4.2 per cent.) showed elephantiasis. If hidden parts such as the scrotum had been examined the rate would have been considerably higher. Of these 51 (5.8 per cent) were men and 13 (2.1 per cent.) women. The incidence was correlated with the age.

Of the 66 persons with elephantiasis 32 (48.5 per cent.) showed microfilariae in the peripheral blood. The microfilaria rate for a total of 1,573 persons of 30 years or over was only 36.6 per cent. The author concluded that "Samoans with elephantiasis had a considerably higher rate of microfilaraemia than did Samoans without elephantiasis, when comparable age and sex groups were considered."

[The author discusses the results and draws his conclusions as if his figures had been obtained on a strictly quantitative basis, whereas the technique adopted would only allow of qualitative results—e.g. the amount of blood taken was not measured but it is stated that it approximated 20 cubic millimetres.]

WHARTON D. R., A. CLEGG, C. & MOYER A. W. Skin Reactions in Sensitized, Infected and Normal Rabbits with Filarial and other Nematode Antigens. *J. Infect. Dis.* 1947 Nov-Dec, 58, No. 3, 54-60. 15 refs.]

Rabbits were sensitized with saline extract of *A. suum* and the filarial worms *Di. immitis*, *immitis* and *Libromonoides car.* and by infection with *Trichinella spiralis*. When these rabbits were tested intracutaneously the different antigens reacted specifically, and there was no significant reaction with filaria antigen in the *A. suum* sensitized rabbits.

"However in the trichinosis rabbits all the antigens reacted strongly. Although *Trichinella* antigen was negative in the heterologously sensitized rabbits.

"There was evidence of reaction by *A. suum* in a few of the two *A. suum* sensitized animals. This may have been due to specific sensitization by obscure ascared infections.

"It is concluded that in skin tests for filariasis cross reactions with intestinal helminths such as *A. suum* do not ordinarily occur.

SCOTT J. A. Studies on the Transmission of the Filarial Worms of the Cotton Rat. *Amer. J. Trop. Med.* 1948 May, 28, No. 3, 461-5.

"A method is described for infecting groups of cotton rats with a known constant number of the filarial worms *Leishmania* or all of which are of the same age. The infections were produced by placing the animals in metal tanks containing numbers of mites whose percentage of infection had been

Helminthiasis

VARGAS L Los simulidos en la transmisión de la Oncocerciasis Americana [Simulium and the Transmission of American Onchocerciasis] *Medicina Mexico* 1948 May 10 v 28 No 555 177-90 [66 refs]

A general account with bibliography

GAYTON, J L BELLIS M & McCLENNAN W H A Survey of Pinworm Infection in an Elementary School. *Canadian J Pub Health* 1948, May v 39 No 5 200-202

The public health nurse in an area in South Vancouver received repeated reports from mothers concerning minor symptoms in their children attributed to pinworms (*Enterobius vermicularis*) The authors therefore examined 145 of the 160 children in the local village elementary school Examination was made by means of the Graham swab (three inches of Scotch tape," held sticky side outwards over the end of an applicator) The swab was then dipped in dilute iodine solution and applied to a microscopic slide for examination

The results are shown in four tables. Altogether 38 children were found positive and 21 others were "known positive" in that pinworms had been seen by the parents. Twelve in the latter group were not examined for *Ascaris*. Thus 59 (37.6 per cent) of 157 children were positive.

There were 116 families represented in the school and 48 of them were shown to have pinworm infection in the family. The median length of residence of these families in the district was only two years. Positive cases were found in every type of family. Infection was highest in the younger children: there were 50 per cent positives in school grades II and III and only 1 per cent in grades V and VI. The geographical distribution of cases was comparable to that of the general school population.

After the examination, the public health nurse visited each of the 48 "positive" families. Symptoms attributed by the parents to pinworm varied from convulsions and coma in one small child to abdominal cramps, nausea, restlessness, poor sleep, anorexia and underweight. In an adult simple pruritus was the only symptom.

Many of the children had been treated previously, so that either the treatment generally used was ineffective or reinfection occurred. The treatment recommended was gentian violet enteric-coated tablets thrice daily in standard dosage in two 8-day series one week apart. The whole family was usually treated, with few complaints of nausea or diarrhoea. Quarsa emmas and ammoniated mercury ointment were also used. Linens and bedding were boiled.

The authors observe that reports in recent journals would suggest that their findings were not unusual and that the percentage of 37.6 found by them would probably indicate a true incidence of some 50 per cent positives. Enteric infection as a public health problem requires further study.

HAEMATOLOGY

STEPHEN J. D. Haemoglobin and Plasma-Protein Levels in West Africa.
Trans. Roy. Soc. Trop. Med. & Hyg. 1948, May, 41, No. 6, 829-31.

Because of the prevalence of dietary deficiencies and anaemias in West Africa, the author in the Gold Coast compared the haemoglobin and plasma-protein levels of troops of the Royal West African Frontier Force with those of the civilian population to determine whether army rationing had any effect on increasing haemoglobin values.

Seven groups of 50 persons each were studied namely (1) African recruits with 6 weeks' service (2) African soldiers with 8 to 8 months' service (3) African soldiers with 2 or more years' service who had been in India, had been on a European-scale ration and in many cases had taken suppressive mepacrine (4) African male civilians from coastal villages (5) African children from coastal villages (6) pregnant African women (7) European soldier stationed in Accra for 3 to 18 months.

The tests were made on 5 cc. quantities of valiated blood (8 mgm. ammonium oxalate mixed with 4 mgm. of potassium valate). The specific gravity of the whole blood and of the plasma was determined by the copper sulphate method of PHILLIPS *et al.* (*Copper Sulphate Method for measuring Specific Gravity of Whole Blood and Plasma* 1943, New York, Josiah Macy Junior Foundation) and the haemoglobin and plasma-protein levels were read from a single line chart.

The results are shown in two tables. The African haemoglobin levels generally were lower than the European, but a high level was found in the soldiers of group (3), as might be expected, in view of their diet and freedom from malaria in most cases. Their mean haemoglobin in gm./100 cc was 15.1 compared with 15.4 for group (7), the European soldiers, and 14.2 for the soldiers in group (2) and the male villagers in group (4). The levels in pregnant women and in children were 11.4 and 12.2 respectively, the frequency of macrocytic anaemia in the pregnant women and of malaria in the children would lead one to expect such figures.

There were no significant variations between the plasma-protein levels in the Africans and in the Europeans.

Since the highest African haemoglobin level was found in the troops who had had a European-scale ration and, in many cases, suppressive mepacrine, the author concludes that "it is thus possible to effect a rise in the African haemoglobin level so that it equals that of the European."

DEWHURST, K. E. **The Normal Lobular Neutrophil Picture in the East African**
J Trop Med & Hyg 1948, June, v 51, No 6, 128-30

The author discusses the principles and significance of the Arneth count and the polynuclear count of Cooke and Ponder and also discusses the findings of a number of workers in the Tropics who found a "shift to the left," both in health and disease [this *Bulletin*, 1937, v 34, 259, 1942, v 39, 54]. He notes that KENNEDY and MACKAY [*loc cit*, 1937] attributed a normal "shift" to climatic conditions, as in the case of Europeans the Cooke-Ponder weighted mean became normal on their return to Europe. In health a lower weighted mean than 2.75 or a higher Arneth index than 58.5 indicates a "shift to the left."

The present author examined blood films from 500 healthy East Africans. 330 were examined in Kenya and 170 in South-East Asia Command. Four tribes were included, but tribal variations in results were negligible.

The Arneth index and the weighted mean were found respectively to be 73 and 2.4, indicating a "left shift" in these Africans compared with the European standards quoted above. In the case of the Africans, the author took the normal limit of the Arneth index to be 65, which is the extreme limit in the European range (given as 51 to 65), and on this basis estimated that 82 per cent of the blood films examined showed a "left shift," which was significant (above 70) in 65 per cent. The figures are shown in tables in the text.

It is suggested that, in addition to the effect of drugs or toxic absorption, an increase of immature neutrophils in the peripheral blood may be stimulated by climatic conditions. The author considers that this is due not to exposure to ultra-violet light, but to the thermal effect of a tropical climate. It is noted that such a shift was found in places with a high humidity (Calcutta) where the effect of ultra-violet rays is diminished owing to their high absorption.

The results show in general that most of the Africans examined showed a "shift to the left" owing to a marked increase of cells of Class II.

[The present reviewer studied the Cooke-Ponder polynuclear in health and disease in East Africans in 1931 (this *Bulletin*, 1931, v 28, 837). He also found some "shift to the left" in a control group which were taken to be healthy Africans but to find the "normal" African, the most careful clinical examination was required in order to exclude any possible factor which might influence the blood counts. In the present author's case, the men examined would of course constitute a much more reliable "healthy" group, since they were controlled troops under constant medical care. The author's suggestion

that the "left shift" might be due to the thermal effect of a tropical climate is interesting, but would require more concrete evidence in its support.)

VENOMS AND ANTIVENENES

TRETHEWIE E. R. & DAY A. J. *New Therapy of Ophidiasis. Austral. J. Exper. Biol. & Med. Sci.* 1948, Mar v 28, Pt. 2, 153-61 5 figs. [17 refs.]

It was found that neo-antergan injected subcutaneously into mice after the previous injection of *Pseustes porphyreus* venom subcutaneously did not reduce mortality.

"Neo-antergan when injected with heparin into mice reduced the mortality following the injection of venom from 50 to 5 p.c.

"A rise of pulmonary arterial pressure was detected in the cat following the injection of this venom but this rise was not affected by previous treatment with neo-antergan.

"The significance of these findings and the rôle of this form of treatment has been discussed."

SERGEANT E. L. *Sur le venin des scorpions *Prionurus australis* L. et *Prionurus acutus* C. Koch. On the Venoms of *Prionurus australis* and *Prionurus acutus*. Arch. Inst. Pasteur d'Algérie* 1948 Mar v 28, No. 1 21-4 1 fig

The author has found by repeated experiments, that the venom of *P. australis* is more potent than that of any of the other North African scorpions. The fatal dose for white mice 20 gm. weight is 1/40-1/20 telson the higher dose causing certain death in 2 hours. In previous studies, Professor Sergeant has compared this with another scorpion which he called *P. lewisii* whose venom is less than one-sixth as toxic 1/3 telson being the m.l.d. for these mice. He now finds that what he has been calling *P. lewisii* is in reality *P. acutus*. He gives descriptions of both these indicating the differences. In a list he gives the lethal doses of the 7 common species of scorpions in North Africa and incidentally shows that the common belief that the black scorpions are the most dangerous is erroneous—the third, fourth and sixth in the following list are black. The m.l.d. is 1 the dried powdered telson *Prionurus striatus* 1/20th telson *P. acutus* 1/15th *P. lugens* 1/12th *P. acutus* 1/10th *Buthus occiduus* 1/10th *Hottentotta genida* 3/4 1 *Scorpio maurus* 7 telsons

DERMATOLOGY AND FUNGUS DISEASES

CALERO, C **Chromoblastomycosis in Panama Report of a New Case and a New Clinical Form** *Arch Dermat & Syph* 1948, Feb, v 57, No 2, 266-71, 4 figs

The author describes an unusual clinical form of chromoblastomycosis in Panama, in which the lesions were not confined to a single area of the skin. The earliest lesion appeared on the antero-external aspect of the left leg as a small nodule which slowly spread until it attained a diameter of 16 cm It was verrucose but not markedly hypertrophic, it bled easily from slight trauma and it was surrounded by a number of satellite nodules A second lesion developed on the back of the right middle finger It measured 5×6 cm and was covered by white, greasy scales, the removal of which caused slight bleeding and exposed a smooth, glistening surface more eczematoid than psoriasiform in appearance Scrapings from both lesions showed the characteristic pigmented fungal cells of the disease, and *Fonsecaea pedrosoi* var *communis* was isolated from these in culture A third type of lesion developed later as a well-demarcated infiltration of the skin, without scaling, excoriation, vesiculation or formation of verrucae on the neck and the flexures of the extremities The fungus was not found in this kind of lesion and it was believed to be an allergic manifestation of the disease

WEED, L A & PARKHILL, Edith M **The Diagnosis of Histoplasmosis in Ulcerative Disease of the Mouth and Pharynx** *Amer J Clin Path* 1948 Feb, v 18, No 2 130-40, 4 figs [65 refs]

In histoplasmosis, a disease of protean symptomatology, the diagnosis rests inevitably on the discovery of *Histoplasma capsulatum* in the lesion, by microscopy or by culture and therefore, accessible lesions such as the ulcerating granulomata which sometimes occur in the mouth are of particular importance for diagnosis The authors describe lesions of this kind in four cases of generalized histoplasmosis In one case, they took the form of ulcers measuring 1 cm in diameter with heaped-up edges, on the faucial pillars and epiglottis, in another, there were multiple small punched-out ulcers near the tip of the tongue which prevented its protrusion because of the pain they caused, in the third case, patches of hypertrophied mucous membrane containing small red nodules simulated epithelioma, but the underlying granuloma was characteristic of histoplasmosis and in the fourth, in addition to granulomatous lesions on the soft palate and neighbouring areas a large ulcer involved almost the entire floor of the mouth and a smaller ulcer was found on the epiglottis. In this last case, seven different diagnoses which did not include histoplasmosis, had been made

In all four cases, the diagnosis of histoplasmosis was based on the isolation of *H capsulatum* in culture from the mouth lesions, but histological confirmation was definite in one case only uncertain in two and wanting in the fourth.

J T Duncan

The action of compounds used as chemotherapeutic agents against blood sucking ectoparasites is highly specific. Thus "pivalyl-1,3 indandione is very effective with lice and relatively inactive against mosquitoes" whereas gamma BHC is much more effective with lice than with mosquitoes.

REPORTS SURVEYS AND MISCELLANEOUS PAPERS

CONGO BELGE. Fonds Reine Elisabeth pour l'Assistance Médicale aux Indigènes du Congo Belge. Rapport sur l'Activité durant les années 1939 à 1945 [BRAUWER, P.] [Report on the Work of the "Foréami" from 1939 to 1945.] 222 pp., 4 maps (1 folding) 15 figs. on 8 pls. & 20 diagrams. 1947 Brussels 112 Rue du Commerce.

The Foréami (abbreviated form of "Fonds Reine Elisabeth pour l'Assistance Médicale aux Indigènes du Congo Belge") is unique among medical and sanitary services in tropical territories. Its purpose is to provide and to maintain for long periods of time in a limited and specially backward part of the Belgian Congo a much more intensive and more costly level of medical care than could possibly be provided for the entire colony. It acts therefore as a spearhead of sanitary progress, which, the authorities hope may gradually move on to new ground, while handing over to the less well-endowed general medical services those areas which have already been reclaimed. Its activities are expected at the same time to provide valuable lessons of ideal practice as patterns which the general medical and sanitary service of the colony may strive to emulate.

The Foréami was founded in 1930, and is run on essentially autonomous lines, though in close association with the colony's general health services. Only the interest on capital funds is spent: the nucleus of the capital has long been provided by 50 million francs voted by parliament, 100 million assigned by the Minister of Colonies, and 245 000 francs donated by Queen Elisabeth. To this are added donations and subscriptions by the general public. The fund is covered by the Foréami has changed gradually from year to year. It began in the District of Bas-Congo but this zone reverted to the general Health Services of the colony in 1934 and activities are now confined within the Districts of Moyen Congo, Lac Leopold II and Kwango covering the needs of about 625 000 people.

Until the war a Report was published annually. For 1938 and 1937 Reports see this *Bulletin* 1940 v. 37 369, 522 1939 v. 36, 408, 636. The activities of 7 years 1939-1945 are reported, with a wealth of statistical detail, in the present volume under date of July 1947.

The Report gives the impression that the Foréami method has a distinct bias towards what may loosely be described as medical rather than sanitary forms of relief—that is, such measures as the provision of hospitals, dispensaries, itinerant treatment teams, etc. rather than the organization of rural sanitation by way of mosquito control, bush burning, attention to water supplies, propaganda, and the like.

Each touring team is in charge of a medical man, and was intended to be responsible for the welfare of 25,000-30,000 people, though the number had later to be increased to 40,000-50,000. The aim is to examine, and treat if necessary, every one of these persons once every six months. A four-year plan of intensified effort was launched in 1939, envisaging the employment of 18 European medical men, 20 European "*agents sanitaires*" and 430 African assistants. The full complement were in action by 1939, but the war naturally interfered with progress, and by 1945 only 10 medical men and 13 "*agents sanitaires*" were in the service.

Details are given, together with photographs, of newly built hospitals, dispensaries and houses. With regard to new roads the war, far from limiting this important development, actually favoured it, because of the military value of a suitable network of road communications.

So intensive and comprehensive have the Foréami's activities been that it is not easy to summarize this work adequately in any space less than is occupied by the original report. In the section on epidemic diseases notes are given for the situation year by year for each of 14 diseases or groups of diseases, such as bacillary dysentery, amoebic dysentery, smallpox, relapsing fever, cerebrospinal fever, etc. There was no frank epidemic of any kind, and there were only 311 deaths under the heading of epidemic diseases among a total of 143,073 deaths from all causes during the 7 years of the Report. There were 1,575,653 vaccinations and revaccinations for smallpox during the period.

Under the heading of endemic diseases, sleeping sickness has long been regarded as the most serious condition, outclassing even malaria in importance. Yaws is fairly prevalent, but is not an anxiety, being easily cured. More serious, but less frequent, is leprosy. There are active foci of pulmonary tuberculosis, very fatal for the African, and venereal disease is common, especially gonorrhoea, with an increasing incidence of syphilis.

When the Foréami began operations, sleeping sickness was a veritable scourge ("*un véritable fléau*"), but it has since been reduced to no more than "*une simple menace*", as a result of systematic and repeated examination and treatment of the population. All other control methods were rapidly found ineffective, mainly through lack of cooperation by the Africans themselves. In recent years, however, direct action against *Glossina* has been taken, especially by means of fly traps of the Harris type, but these efforts have met with little success. Increasing reliance has been placed on mass chemoprophylaxis, with pentamidine or propamidine replacing suramin (Bayer 205) for this purpose. Because of its activity in the nervous stages of the infection tryparsamide remains the sovereign remedy for established cases, in spite of the increasing incidence of arsenic resistance. The most effective treatment for arsenic resistant cases is a combination of suramin and tartar emetic. Out of a total of 58 505 cases of all types treated by all methods since the start of this work, 86 per cent have been cured. A striking epidemiological finding is that "the existence of an arsenic-resistant strain generally provokes a veritable epidemic flare-up, due probably to the considerable virulence of the trypanosome and its extreme transmissibility" (page 76). [This does not accord with VAN HOOFF's views (this *Bulletin*, 1947, v 44, 1048, also quoted by PELLISSIER, this *Bulletin*, 1947, v 44, 975) on decreased transmissibility associated with arsenic-resistance.]

A considerable section of the report deals with the SADAMI (*Service Auxiliaire d'Assistance Médicale aux Indigènes*), the name given to the activities of individuals or organizations not dependent directly on the government, and which are mainly various religious missions.

Appendices deal with (1) a general survey of pathological conditions encountered in the Congo, by A. FAIN, (2) Chemoprophylaxis experiments with propamidine and suramin, by A. FAIN and DRUMEL, and (3) the "buaki

or kibengi syndrome (see this *Bulletin* 1946 v 3d, 91-113) by DUMAIL and G. GELIKAS.

In some future Report of the Foréani it would be extremely valuable if a careful comparison could be drawn between health conditions in the Foréani zones of activity and similar perhaps neighbouring areas which have not had such preferential treatment. It would be worth while knowing whether the extra benefits derived are fully commensurate with the extra care and costs expended.

DEVORS P. Le Touat, étude géographique et médicale. (Geographical and Medical Description of Touat. *Arch. 1st de Pasteur d'Algérie*, 1947 Sept. Dec. v 25 Nos. 3, 4 223-74 3 figs. (2 maps) and 6 pls.)

In this monograph the author gives an interesting account of the geography, history, sociology and disease prevalence of Touat where he had spent two years as a medical officer. Touat consists of a group of oases in the central Sahara extending over 230 km. from north to south. The northern end lies to the south west of Laghouat.

The population consists of Arabs and Negroes. Their mode of life, manners and customs are well described and some good photographs reproductions add to the interest of the story.

Diseases of the eye are almost universal. Trachoma and acute conjunctivitis are both widespread. *Weeks bacillus* or *Morax diplobacillus* are responsible for the conjunctivitis. Gonococcal conjunctivitis was not seen.

Malaria is endemic but the endemicity is of low intensity. From time to time exceptional circumstances have caused epidemic malaria. Thus in 1945 the opening of a *foggara*—an underground water channel, a kilometre from Adrar the capital, resulted in the formation of a marsh which provided good facilities for mosquito breeding—an epidemic of malaria followed which lasted from June to October. The spleen rates everywhere are very low. Of 77 patients blood smear examined, *P. falciparum* was found in 44 (1 in 20), *P. malariae* in 12, and a mixed infection in one. The only three mosquitoes that have been identified in Touat are *A. gambiae*, *A. sergenti* and *Theobaldia longipalpis*.

Louse borne relapsing fever had never been seen in Touat till 1945. In 1946 there was a large outbreak. The author saw and treated 716 cases. Arabs and Negroes were alike affected. The case mortality rate was highest among the Negroes who are less well fed. A case was seen in infants under two years of age. Untreated cases often succumbed. Jaundice was a common symptom.

In 1941 and the two following years there were outbreaks of typhus fever. Neither typhoid fever nor Malta fever occur. Only two cases of cerebrospinal fever have ever been diagnosed. Sporadic cases of diphtheria are seen from time to time. Tuberculosis is not very widespread. Smallpox once very prevalent is now rare thanks to vaccination. Epidemics of chickenpox have occurred. A serious outbreak of measles occurred in 1945—more of 74 observed cases terminated fatally. Scarlet fever has never been seen.

Veneral diseases are very widespread. *Chlamydia*, gonorrhoea and soft chancre are all common.

Organic diseases of the heart are rarely observed. Acute rheumatism was not seen. Bronchitis is a common malady. Dysenteric syndromes are prevalent in May, June and October when flies are most prevalent. Clinically the cases resemble bacillary infections. Amoebic infections appear to be rare.

Famine oedema was common in 1944-45 and followed a series of deficient harvests. Some 70 per cent of the population in Larbaoua starved.

There are no poisonous snakes. Scorpions are frequent but their sting is rarely cause of death.

Norman H. Cole

UNITED NATIONS DEPARTMENT OF SOCIAL AFFAIRS POPULATION DIVISION
Lake Success, New York **The Population of Western Samoa** *Reports on
the Population of Trust Territories No 1* 1948, Jan 17, 61 mimeographed
pp, 7 figs [Refs in footnotes]

In a prefatory note it is explained that " This is the first of a series of reports on the population of Trust Territories, being prepared by the Population Division in the United Nations Department of Social Affairs. The purpose of the reports is to summarize existing knowledge regarding characteristics of the population, trends of population growth, and the relation of population to economic resources in each of the territories."

The particular interest of the islands which form Western Samoa lies in the fact that the population, of about seventy thousand, is one of the most rapidly growing populations in the world. An attempt is here made to gather together all known statistics relating to it and to discuss the factors which may have contributed to this rapid increase.

The writers have, the reviewer believes, been successful in collecting all the early estimates of population starting with that which has been attributed to La Perouse (1787). These early estimates were made at irregular intervals over a period which ended in 1886, that is to say for almost exactly a century. The evidence seems to suggest that in that period the population occasionally rose above forty thousand or fell below thirty thousand, but that there was no general trend over the whole period. It seems clear that such diseases as influenza and whooping cough, which were probably introduced to a non-immune population by European shipping, produced serious epidemics and sudden reductions in the population. The report refers also to wars between different sections of the population — it is felt that hardly enough weight is given to the fact that in the nineteenth century wars had become much more deadly because the Samoans possessed weapons made of iron, and also firearms. There is little evidence that famine reduced the numbers of people.

The second period may be said to have started with German occupation of the islands in 1900. From then until 1914 a census was made on several occasions, and in 1905 regulations were brought in for the registration of births and deaths. Throughout the period of German occupancy and, indeed, up to 1920, one may say that the population appears to have increased rapidly but to have been reduced occasionally by major epidemics. Much the most serious of these is described in the following words — During the last three months of 1918 influenza struck with such violence that it not only wiped out all the gain of the preceding seven years but reduced the population to a level below that of 1911. The number of deaths reported in 1918 was over 8,400 or 7,000 more than the number of registered births. The loss amounted to nearly one-fifth of the whole population. This ranks as one of the most disastrous epidemics recorded anywhere in the world during the present century, so far as the proportion of deaths to the population is concerned. As a result, when the next census was taken in April 1921, it showed practically the same population as in 1906.

The authors call attention to the fact that throughout this second period (1900-1920) the population manifested a succession of sporadic increases interrupted by precipitous declines — this as they say, is characteristic of a rather primitive population with a high birth rate subjected to periodic catastrophes.

The third period dates from 1920 when the League of Nations granted a Mandate to New Zealand. Since that date there has been no major epidemic and the general health of the population has been steadily improved. In each year the registered births have exceeded the deaths and the population has

nearly doubled in less than a quarter of a century the average increase being 2.5 per cent per annum. This average rate of increase is greater than that recorded for any other tropical area—for instance the Philippine Islands, in which the rate of increase is well known to be very great has had an average of 2.3 per cent. over a comparable period.

Other parts of this interesting document discuss the proportion of leprosy and people of mixed blood in the Samoan population, also birth and death rates, and immigration and emigration. One receives an impression that the text has been written at least in part by men familiar with the problems on the spot and fully aware of the difficulty of accumulating vital statistics through illiterate headmen literate only in a Polynesian tongue. It is noted also that the report gives due and expert emphasis to social conditions—for instance the section on the density and distribution of the people is closely related to that on the economic development of the country.

The final chapter discusses the probable future of the Samoan population, which will have reached about 150,000 by 1975 if the present rate of increase continues—that would give the very high density of 250 per square mile of cultivated land. Clearly then there is an urgent need for the study of rural economics and agriculture and for the improvement of agricultural methods so as to ensure that the increase of food will at least keep pace with the increase of population. The writers also enter an urgent plea for a more complete statistical study which would give facts of age distribution, fertility, mortality in relation to social conditions and so forth.

P. A. B. H. S.

MANSON BARR, P. *Scottish Pioneers in Tropical Medicine*. Edinburgh Med. J. 1948, Apr. v. 53, No. 4 220-31.

An interesting series of biographical sketches of some of those who have attained to fame in tropical medicine after medical training in one or other of the Scottish centres of learning, Aberdeen, Edinburgh and Glasgow. Sir Philip starts with James Lind who lived through the greater part of the 18th century and is known mainly for his work on scurvy and the diseases of seamen. (There was another James Lind contemporaneous with him who also served in warm climates and is often confused with the former.) More than a score of eminent tropical pioneers in medicine are spoken of—Crainger and the dysenteries, Wright and yaws, Livingston and head, Cribb and the parasitologist Pinkerton the first lecturer on tropical medicine in Edinburgh, Timothy Lewis and D. D. Cunningham friends and colleagues and both Fellows of the Royal Society. Lewis has been called the Godfather, as Manson the Father of Tropical Medicine. So to more recent times to men but lately with us and known to present-day Fellows of the Royal Society of Tropical Medicine and Hygiene: Cantlie, Leishman, Mook, and, lastly, those whom we fortunately meet in the flesh today: G. Carmichael Low whose work rewarded experience in the Roman Campaigns are known to all, Professor R. T. Leiper, helminthologist of worldwide reputation for his work and discoveries on Loa loa, Guinea worm and schistosomiasis, or Malcolm Watson remarkable for his work on malaria and species sanitation and the first Director of the Ross Institute.

The article fittingly begins with a quotation from Longfellow *Psalm of Life* and, not so aptly, ends with a misquotation from the same poet *Life's a Journey*. "The heights by which men are led and hope—the author being perhaps led away by the example of Scotland's national poet who rhymed *Loch Leven* with *the* *ye*."

BOOK REVIEWS

SCHAPER, I [Professor of Social Anthropology, University of Cape Town]
Migrant Labour and Tribal Life A Study of Conditions in the Bechuanaland Protectorate pp vi+248, 1 folding map 1947 London New York
 Cape Town Geoffrey Cumberlege, Oxford University Press [18s]

For the past seventy years or more, Africans of Bechuanaland have been leaving their homes and the influence of tribal life to work in the Union of South Africa, a very large proportion to be employed on the Kimberley or South-West African Diamond Fields or the mines of the Witwatersrand. Except in the tsetse-infested Okavango swamp area of the north-west, the scarcity of surface water is the chief single natural difficulty to be combated by the African cattleman and farmer of Bechuanaland, this scarcity is extreme in the 135,000 square miles of Kalahari Desert in the west and south-west. The small population of this desert area consists essentially of Bushmen with an admixture of Bantu blood, of Bantu stock the Tswana are the dominant group and form the ruling communities of all the principal tribes inhabiting the more fertile eastern districts along the boundaries of the Transvaal and Southern Rhodesia, amounting to some four-fifths of the total population of 250,000—with a density of 3.9 persons per square mile. Water shortage and primitive agricultural methods make life hard for the Bechuana and it is not surprising that men are readily attracted to industrial work with its regular wage, a migration which in 1913 amounted to 35 per cent of male adults, one third of these were enlisted in the military Pioneer Corps.

The economy of the Bechuanaland Protectorate must be seriously affected, tribal authorities complain that the welfare of the people is suffering, herding of cattle is difficult, farming is incomplete and inadequate—these effects are counterbalanced at least partially, by cash income received from the migrants. In addition, ancient tribal institutions have been affected by the activities of a European administration, by missionaries and by traders. Observations have been recorded on the spread of disease, notably tuberculosis and syphilis introduced from industrial areas, on decay of tribal discipline, on laxity of sexual morals and on an apparent decline in the birth rate.

What of the effect on the migrant personally? Physical results will depend on his environment. On the mines he has to work hard, but in return is looked after in many ways—he receives, for example, a balanced diet and free and immediate medical attention with consequent improvement in physical condition—this is not sustained, unfortunately, when he returns home. In other occupations especially where food and quarters are not provided health is more likely to suffer than to improve, mainly because of an unbalanced diet and insanitary surroundings. The illiterate Bechuana is little affected mentally by his sojourn in the industrial areas and on return to his country slips back readily into his previous and traditional mode of life with perhaps some resentment of tribal authority or discipline. The partly educated Tswana on the other hand may get a relatively good job away, and returns home with a broader outlook and is generally a more useful member of his tribe. Some remain away permanently and are 'lost' to their tribe.

Though this book is of interest mainly to South Africans the material presented covers the impact of highly organized and rapidly progressive European industrial undertakings on the economically self-sufficient African inhabitants of a vast bounding territory over a period of sixty years. The objective detail of methods, causes and effects of migration makes most interesting reading and should prove valuable to those whose duty it is to watch the interests of the African tribal area and to the residents of

Britain who for political or business reasons is interested in the development of East and Central Africa. The final chapter deals with some possible remedies bearing in mind that Bechuanaland is only one of many sources of African labour for South African and S. Rhodesian industry.

Dribbulation is not inevitable and every encouragement should be given to the maintenance of contact between migrant and home by improved organization at the site of industry by contracts which permit of regular return home and by ease of transportation. Most important of all is the alleviation of the difficulties of life of the general population and the coincident encouragement of a larger proportion of males of the 20-40 age group to remain in their home territories by improvements in the administration involving education, health and welfare services and methods of agriculture and animal husbandry. Restriction by statute of the numbers of migrants is not recommended.

This book is the outcome of a request by the Bechuanaland Protectorate administration to the author to study the effects of labour migration on tribal life and contains useful statistical information in eight appendices and forty three tables.
R. Ford T. Cole

UNITED STATES PUBLIC HEALTH SERVICE AND TENNESSEE VALLEY AUTHORITY
Malaria Control on Impounded Water pp. xiv+422, 15 figs. 1947
Washington D.C. U.S. Government Printing Office

The Tennessee Valley Scheme vaguely reminds most people of the New Deal and the development from a primitive to an advanced state of a large tract of land. To malarialogists, it is one of the foremost examples of ambitious malaria control, in its way unique and the Mecca to which they turn when they reach the United States. Vast water conservation, irrigation and hydroelectric works have been created in a potentially malarious country where the principal vector *Anopheles quadrimaculatus* chooses the edges of impounded waters as a preferential breeding place. The necessity for malaria control has been recognized from the start and it has been integrated in the engineering works as an essential part of the scheme. Success has been complete and by 1945 a potentially epidemic year only 20 out of 15,338 blood films taken from inhabitants in 1943-1944 were positive (see this Bulletin 1947 44 891).

For the first time the methods used are fully described in a book prepared under the direction of Dr E. L. Bishop and M. H. D. Halls and edited by Mr C. I. Mansur. To some extent the title is inadequate for it deals at length with the morphology, bionomics and ecology of the North American anophelines, the parasitology and epidemiology of malaria and the conduct of malaria surveys, as well as malaria control by all established methods except drugs, prophylaxis. It thus constitutes a complete textbook of malaria control under American conditions whatever the ultimate origin of the vector might be.

The chief interest to the non-American reader lies in the first half of the book which deal with the management of impounded water on which it constitutes an authoritative statement such as is not available elsewhere. There is a well illustrated and fully detailed account of every process in the prevention of mosquito breeding from the time of the first decision to create a reservoir through its construction to the time of its routine patrol.

When a reservoir is first projected detailed maps are prepared showing the probable extent of anopheline breeding, around its perimeter any necessary changes in the original plan are then made and a control scheme outlined for every foot of water. Usually the first step is clearing and drainage of the margins to give sharp water edges leaving no emerging terrestrial vegetation under the water to be flooded, a clear stretch above the normal water line where the

flotsam carried by floods can be stranded without embarrassment to subsequent control, special provision for the stranding of debris in some areas, and no hollows likely to hold water above normal water line on the subsidence of floods. On formation of the dam, the main object is to keep clean shore lines, mainly by water level management and plant control. During the mosquito season a regular cycle of fluctuation in the water level is followed and discourages breeding both through its direct action on larvae and its indirect effect on the vegetation which is essential to them. The cycle varies with the type and function of the reservoir, some types being less discouraging than others, but in all cases it produces a marked reduction in breeding and in the need for

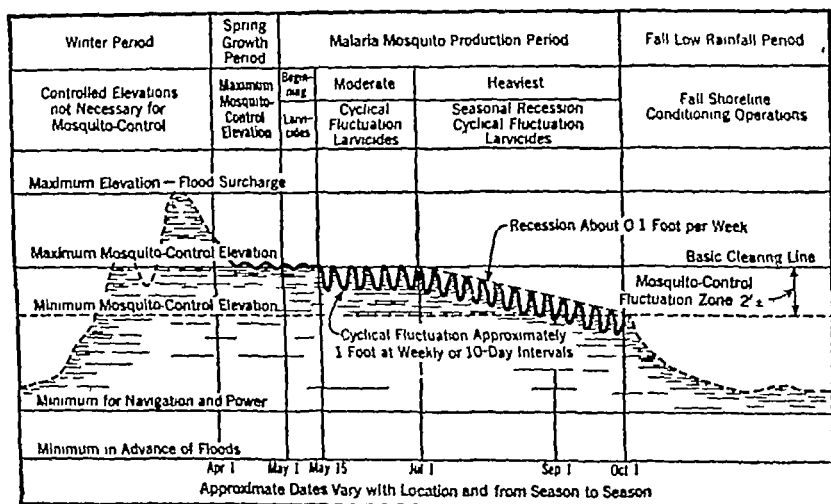

FIGURE 50 —Desirable phases of water level management for mosquito control on main river reservoirs.

[Reproduced from 'Malaria Control on Impounded Water']

larvicides Plant growth is modified by many methods, including, besides water-level-management, the use of selective hormone and conventional herbicides, the management of grazing, mechanical clearance and others which are fully described

Where these measures are inadequate, larvicides are used, mainly DDT. Most are applied from aircraft, and the book gives a good account of air practice, but all varieties of mechanical, semi-mechanical and hand distribution are used from the shore and the water. As prevention of breeding may be temporarily either impossible or uneconomic, control measures extend to the mosquito proofing of houses and the application of indoor residual insecticides.

The book is well got-up and both freely and ably illustrated with sketches, plans and photographs, coloured where that is helpful to their interpretation, there is no phase of mosquito control which it does not cover in an able manner. Though written with the object of illustrating American technique and referring only to American anophelines it is a text book of malaria control which will be of great value wherever the English language is read. The reviewer's sole criticism is perhaps ungenerous as it is one of excessive modesty. The Tennessee

Valley Scheme is nowhere described as a whole entity. Though every method used on it is given in full one could read the book unaware of its scope, of the organisation involved in a work of this magnitude, or of the relative importance of the different measures in the whole scheme. Even the few elementary facts at the start of this review have come from the reviewer's general knowledge and he still wonders what are the complications involved in treating 10 000 miles of shoreline.

AMARAL, A. DARIO F. PONTES, J. FERNANDES & PIRES Carlos D. de Avila. *Amoebíase. Estudo etio-patológico, clínico, terapêutico e epidemiológico. [Amoebiasis. A Pathological, Clinical, Therapeutic and Epidemiological Study]* 355 pp. 48 figs. 1947. S. Paulo: Tipografia Rosalillo Rua Rui Barbosa V. 333.

This work originated in a study of Intestinal Amoebiasis in Brazil to be followed by a report of more work on the medico-social problem of amoebiasis. The present volume is the outcome of a collaboration between the departments of parasitology and clinical medicine of the São Paulo University and the medical officers in charge of the penitentiary and the gastro-enterological clinic of Santa Casa.

After an introductory chapter in general terms, there follows the first part dealing with the parasitological aspect starting with the story of the discovery of amoebae in man, *E. gingivalis*, by GROS in Russia a century ago (1849) and *E. coli* by LEWIS and CUNNINGHAM in cholera stools in 1870-71 and of LÖSCH's amoeba in dysentery in Russia (1873) though Lösch did not recognise its pathogenicity. KOCH (1883-87) and HARTWIG in Egypt (1884). Next is considered the pathogenicity or non pathogenicity of various amoebae—*E. coli*, *E. histolytica*, *E. tetragena*, *E. musalis*, *Endolimax nana*, *Iodamoeba butschlii* etc.—and there follows a long discussion on nomenclature and an account of the morphology and biology with good illustrations and graphs indicating the sizes of the cyst forms. A subsection of this part is concerned with the action of the amoeba on man, with a setting out of the different views regarding its pathogenicity and the results of animal inoculation, bearing in mind that some laboratory animals may be naturally infected by amoebae. The statements in this chapter as indeed throughout the work are well documented and illustrated by quotations in the original.

Part II considers the pathological anatomy with very fine reproductions of the lesions in various organs of the intestine large small and appendix and the presence of granulomata (amoebomata) also in the liver infected in being brought there by the blood stream, by the lymphatics (not admitted in some writers) by the peritoneum, and by direct extension in the lung by continuity and by embolism and in the brain.

others passing cysts but presenting no other symptoms. They quote Craig as saying that constipation is a frequent symptom in carriers, in fact, the rule rather than the exception, and cases are quoted in support of this. In this section also observations and comments are made on hepatic and pulmonary amoebiasis.

Part IV, *Diagnosis*, takes up the methods in turn. Direct examination, culture, animal inoculation, sigmoidoscopy, with records of cases, complement fixation with an aqueous extract of faeces or of pus from a liver abscess in an experimental kitten, or Craig's alcoholic antigen, or Stone's cyst antigen, the intradermo-reaction with mucus and fragments of intestine in saline from a case of acute dysentery, by radiology revealing local spasm. A table is given, adapted from Craig and Faust, for distinguishing the cysts, in Lugol's iodine or stained by iron haematoxylin, another table from the same authors gives the distinguishing features of the six amoebae mentioned above, stained and unstained. The authors record that in examination of 2,727 samples of faeces 220 were positive, the numbers at successive examinations being 115 (52.2 per cent), 41 (18.6), 29 (13.1), 16 (7.2), 15 (6.8) and 4 (1.8).

Part V, on *Treatment*, begins with a general survey of the indications and then speaks in more detail of (1) Alkaloids—kurchi, cinchona, *Chaparro amargosa*, and ipecacuanha derivatives. (2) Quinoline derivatives—yatren, vioform, diodoquin. (3) Arsenicals—trivalent (606 or sanluol, and 914, neosalvarsan) and pentavalent (treparsol, stovarsol, carbarsone). (4) Others—liver, liver extracts, cod liver oil, E B I, adrenaline, bismuth salts, etc. Lastly dietetic treatment. The authors give the views of others and then their own, stating that they place most reliance on emetine, but stressing that to be successful it must be given early, intensively, intermittently and periodically.

The sixth and final part considers *epidemiology and prophylaxis*. A map on a very reduced scale, but nevertheless fairly clear, of North and Central America shows the districts affected and there is a table quoting the incidence figures in the eastern hemisphere as recorded by various authors. There is another map of South America and a table giving various records of the names of investigators, the number of examinations carried out by them and the number found positive, in Canada, different parts of the U S A, South America and the West Indian Islands. Another map, on a rather larger scale, indicates the parts of Brazil where investigations on prevalence have been carried out and the results recorded by observers in the different States are quoted. Thus, in São Paulo alone 35 records are quoted in which the numbers examined ranged between 18 and 5,429 and the percentages positive between 0.1 and 50.39. Though detailed, these figures are not very informative. For example, one figure of 38.8 per cent positive is based on examination of only 18 apparently healthy persons and the 50.39 on 127 believed to be healthy. The highest number examined, 5,429, were of specimens sent to the laboratory in the Capital District as long ago as 1917, and among these only 10 per cent were positive. The question of age incidence is referred to, but here again little can be learned, because the records are based on very few cases and in limited localities. Nothing new is said on the mode of conveyance or on prophylaxis and both are dealt with in a few pages.

To sum up. The information in this book is well set out, interestingly expressed and clearly printed. To have accomplished such a task of collating information and assimilating to it their own investigations must have demanded wide research and it is most useful to have all these facts brought together in a single volume. The sections are well balanced, none being given disproportionate space. The clinical cases detailed, though few, have been carefully selected—they might be increased with advantage. References number nearly 500 from more than 250 authors from all over the world. Full credit has been given to other

workers in this field. In short this is a book which should certainly be at hand for reference by anyone interested in the subject of amoebiasis.

H. Harold Scott

VAN THIEL, P. H. [Professor of Parasitology of the University and the Institute of Tropical Medicine at Leiden.] *The Leptospiroses*. pp. x+231. 19 figs. on 8 pls. & 5 text figs. 1948. Leiden Universitaire pers. Leiden. (L1650) [Review appears also in *Bulletin of Hygiene*]

This book is a useful addition to the literature on leptospirosis. It should prove of value both as a work of reference and as a guide to those who have to undertake epidemiological investigations in the field. The clinical side of the various leptospiroses is less adequately covered. The full report of work done in Holland and Indonesia is especially welcome because much of it was not readily available to English readers.

After a chapter on the morphology of leptospires the unitary and pluralistic views on the species problem are discussed. On the epidemiological and experimental evidence the author accepts Schüffner's classification—“special” types are ranked as species if more or less sharply defined differences exist in (1) antigenic structure (2) epidemiological behaviour with respect to carrier hosts (3) behaviour in experimental animals (4) geographical distribution (5) clinical characters of disease produced in man. This outlook has practical advantages. If serum treatment is employed the specific serum must be administered. This would be impossible if the diagnoses were merely “leptospirosis”. Preventive measures too may vary according to the carrier host.

The third chapter contains full details of the laboratory methods required in the isolation, culture and serological identification of leptospires. Criticisms are made of the different methods and suggestions are made to the appropriate occasions for their use. This chapter is particularly valuable. The information it contains was scattered throughout the literature in a number of languages, and has never before been brought together.

Epidemiology is the subject of the next chapter. Infection by direct contact with urine containing leptospires is not common, except perhaps in the case of *L. canicola*. Attention is therefore directed mainly to the means by which water is contaminated by carriers, to the conditions necessary for the survival of the organism, and to the most likely method of infection in man. Techniques are described for isolation in urine, and leptospires in unpolluted water.

Prophylaxis is considered shortly under (1) Destruction of leptospires by drainage of slumps or altering the acidity of waters when practicable though the use of calcium cyanamide as a fertilizer proved futile in the rice fields in Japan. (2) Destruction of carriers and growing of budlings and swarming pools against rats. (3) Protection of person at risk by the wearing of rubber boots and gloves when prophylactic animals are used.

Chapters on the pathological and biochemical changes and on the symptomatology in man complete the central part of the book. The method of presentation was doubtless used to advantage in later editions. It may be the best possible but the result is not infallible. The manifestations of leptospirosis are so diverse and the benign forms differ so widely from the severe varieties that the reader is left without any clear clinical pictures.

In the second half, each leptospirosis is considered individually, special attention being given to epidemiology and experimental studies in animals.

The symptoms of the diseases in man receive relatively little notice, but the other aspects are very well treated

The book is well written and produced, but lacks a subject index

LEMIERRE, A *et al* [Edited by] *Traité de médecine, Vol 2 Maladies infectieuses (seconde partie) Maladies parasitaires* [Treatise of Medicine - Vol 2 Infections and Parasitic Diseases] 955 pp, numerous figs 1948 Paris Masson et Cie, 120 Boulevard Saint-Germain [1,950 fr, £2 10s 0d]

The second volume of this Treatise of Medicine, which is a very considerable work of seventeen volumes, deals partly with infectious diseases [most of which occupied the first volume] and largely with parasitic diseases. About 700 of its some 1,000 pages deal with diseases due to parasites and fungi and those caused by bacteria or viruses which might properly be called tropical diseases. These are dealt with systematically and, in the case of some of the more important diseases, at considerable length. Historical, geographical, epidemiological, pathological and clinical aspects are dealt with, transmission and vectors are discussed, and diagnostic, therapeutic and prophylactic methods described.

There is a noticeable variation in the emphasis on the different conditions and their features. For example, the chapter on malaria occupies over 80 pages which cover the subject widely and include references to recent (but not the most recent) work on the exo-erythrocytic stages of the parasite, on the other hand, although there is a brief reference to the drug SN 7618, there is none to paludrine. Again, there are 35 pages dealing with epidemic typhus and 5 with murine but mite-borne typhus only occupies a page and a half and is separated from the typhus group as a subdivision of "exanthemata transmitted by mites or ticks". It would not be reasonable to expect that so tremendous an undertaking as this series of volumes, the preparation of which must inevitably occupy a very long period, should contain the most recent advances in the knowledge and treatment of the diseases concerned. Most of the references are prior to 1945, so that the bulk of the considerable amount of material published since then is not available.

Nevertheless, the volume contains a vast amount of detailed information. There are numerous references, largely in the form of footnotes in the text. The work is fully illustrated with photographs, diagrams, drawings, and a few excellent coloured plates. Many of the photographs might with advantage be reproduced more clearly.

The field is widely covered and there appears to be no tropical condition of consequence which is not dealt with. The volume has been prepared by an imposing team of some 30 collaborators and the list includes a number of recognized authorities whose names will be familiar to workers in tropical medicine.

There is a full table of contents, but the absence of an index in so large and detailed a work is a disadvantage.

H J O'D Burke-Gaffney

HUBBARD Clarence Andresen [Formerly Head of the Department of Biology and Director of the Pre-Medic Curriculum, Pacific University, Forest Grove, Oregon] *Fleas of Western North America. Their relation to the Public Health* pp ix+533, numerous illustrations 1947 Ames, Iowa Iowa State College Press [36s]

The great part of the book consists of a taxonomic consideration of the fleas known to occur in North America west of the hundredth degree of longitude.

This is prefaced by general introductory matter including an account of the relation of these insects to public health, and followed by host indices and so forth.

Such a work might well be solid but tedious. The author has been successful in killing this, and in communicating some of his own personality and enthusiasm. He leads off with an account of the work and personal careers of three pioneers, C. F. Baker, Nathaniel Charles Kothschick and Earl Jordan, the last two of whom are described as "the inseparable English duo." The author then sweeps on to the period following the introduction of plague in California in 1900 and writes of new workers who were attracted to the study of the entomology of the disease. From that point he continues right on to 1944 mingling entomology, personal notes, photographs of workers and references to plague in the area. A section on the medical importance of these insects follows. It deals mainly with plague and describes what has occurred in the States of Western North America. It seems that in North America as a whole since its inception into man in 1900 there have been 506 human cases with 343 deaths. On a later page the author puts together all the records of the recovery of *P. pestis* from rodents in North America. One notes that the bacillus has been recovered from members of eighteen of the thirty genera of rodents.

The author then passes on to deal rather sparingly with typhus but here we feel that he is not on sure ground for he distinguishes fundamentally between the typhus of the Old World and of the New and regards murine typhus as a characteristic disease of the New World only. He then reviews our knowledge of the infection of fleas with *Brucella tularensis*, a matter on which North American workers have made most valuable contributions. The introductory section is concluded with paragraphs on fleas as pests of house or farm and on the development of allergy towards these insects. This is followed by practical chapters on trapping small mammals, the technique of mounting, and the external anatomy of fleas with special reference to identification. One notes that in several places in this text the author recommends kerosene as an insecticide and suggests that one should kill flea larvae by watering them with salt water.

The systematic part of the book runs to more than 300 pages and follows conventional lines. It includes not only the distinguishing anatomical characters of each species but data on biology and seasonal and geographical distribution within Western North America. The host records seem to be very full and in nearly every case the species of host is given a Latin name, an excellent point. One notes that *Tunga penetrans* is listed because of its possible future importance though it has not yet been identified in the area. *Imex ricinus* is common and widely distributed and occurs on many species of birds including wild carnivores. *Cimex phylodes fuscus* is a serious nuisance to man in summer and early autumn, and some individuals become venereal. It is suggested that they should be treated with flea antigen. *Amblyderes* is recorded from several Western States and British Columbia.

The last part of the book lists the 46 species of flea known to occur in Western North America and shows their occurrence in the separate States (California with 102 species heads the list). A similar index is given of the distribution of 136 species of fleas unknown to the West in the Eastern States. There are then a total of 37 pages on North American fleas and only ten spread from the Atlantic to the Pacific Coast. A valuable feature of the book is the "host index" which is a list but not a detailed register of all the hosts of fleas and all fleas on certain other groups including man on which fleas have been found in the area. Under each of these host groups there is a page or two of notes on biology of the species of fleas found on that host. The bibliography gives a continuation of that published by Jellison and Brown (1947).

Vol 45, No 9]

Book Reviews

The book contains an immense amount of local information and will be valued by specialists. The English is often prolix but the author's meaning can be made out. The proof-reading has not been completely successful.

P A Burton

JETHIER, Vincent G [A M, Ph D, Professor of Zoology and Entomology, Ohio State University, etc] **Chemical Insect Attractants and Repellents** PP vi+289, 69 figs 1947 London H K Lewis & Co Ltd

The author feels a natural dissatisfaction with the present state of our knowledge about substances which are attractive or repellent to insects and about their mode of action. He has gathered together a large body of empirical foundation for an improved understanding of the subject.

The book covers a wide ground and represents much reading. The author opens with general chapters which give some idea of the type of response that may be observed when insects are exposed to physical stimuli such as odours or humidity. The insect's reactions to stimuli of this type are related to its needs for food, attraction to members of the opposite sex, recognition of members of its own species, discovery of a place in which to lay eggs, and so forth. This is followed by several chapters giving information on the reactions of insects to certain groups of chemical stimuli, e.g., the essential oils, products of fermentation, substances that result from the decomposition of fat, protein, etc. The author also gives attention to physiological methods and apparatus by which one may study and compare these responses. In dealing with baits and traps, the subject is considered generally. The author has wisely omitted a mass of empirical formulae and has not discussed the detailed relation of this type of work to the control of insect pests.

In passing over from attractive to repellent substances, the author reaches a part of his work which is of more immediate interest, perhaps, to the readers of this *Bulletin*. There are sections dealing with repellents against blood-sucking flies, house flies, harvest mites (*Trombicula*) and so forth and these give a good up-to-date account of the subject. It is clear that the author is familiar with both British and American published work. It would perhaps have been welcome if he had felt able to give more attention to the achievements and limitations of some of the most effective repellents such as dimethyl phthalate, Indalone and extracts containing pyrethrum.

The book covers much ground on the borderline between biology and chemistry, the general attitude being careful and scientific. It is hardly possible in the present state of knowledge to discover the principles which may be involved, but the book is likely to be influential in the development of the subject.

DANIELSSEN, D C & BOECK, C W **Atlas de la Lèpre** Bergen en Norvège 1847 [Atlas of Leprosy] (Édition commémorative du centenaire) [Re edited by H C de Souza-Araujo] 1946 Rio de Janeiro

Professor de Souza-Araujo has performed another service to leprologists. He has re edited the Facsimile of Danielssen and Boeck's original *Atlas of Leprosy* and brought it out (in monochrome) in commemoration of the work first published in colour in Norway in 1847. Professor de Souza-Araujo had three objects in view in undertaking this issue. First, to keep green the memory of the two famous Norwegians, Daniel Cornelius Danielssen and Carl Wilhelm Boeck, who may justly be regarded as the founders of modern leprology, second, to help the International Leprosy Association to re-establish, or at

least to re-organize the Bureau and the International Journal of Leprosy at Manila University destroyed by the Japanese in the last war by presenting to it the proceeds—a most munificent gesture as the Professor would doubtless reap a rich harvest from the sale of such a work. His third aim was to make the younger workers in this field acquainted with the sterling work of their predecessors.

The price affixed to the *Atlas* is \$3.00 (U.S.A.) or £1 which should be sent to Dr. Ernest Muir, Secretary-General of the International Leprosy Association, 167 Victoria Street London S.W. 1.

The *Atlas* comprises two portraits of Danielssen and one of Boeck, and 74 black and white plates full page and beautifully reproduced depicting the many forms and stages of the disease. Appended is a facsimile reproduction of the title-page of the original treatise on leprosy or "Elephantiasis des Grecs" as they called it which accompanied the original *Atlas* of coloured plates, published by J. B. Baillière in Paris and H. Baillière in London.

Tropical workers owe a twofold debt to Professor de Souza Araujo for his thought of bringing out this volume and for the excellence of his accomplishment.

H. H. Old Scott

SCHÖN, Rudolf *et al*. Internal Medicine. Part I. First Review (German Service 1939-1943). 708 pp. 18 figs. 1943. Published by Office of Military Government for Germany. Field Information Agency. Technical British, French, U.S.

This volume written in German in the FIAT series of publications designed to inform international science of research done in Germany during the war years, reviews the work undertaken in connexion with "internal medicine."

Almost half of the 388 pages are occupied by the first chapter which reviews work done on infectious diseases: these include bacillary infections, rickettsial diseases, virus and protozoal diseases with briefer references to myxomatosis and general theoretical considerations. This chapter includes brief reference to cholera, some ten pages dealing with typhus and a similar number with malaria and amoebic dysentery. In the last two-thirds the paper deals largely with the wartime lockdown and treatment of the diseases.

The remaining six chapters deal with work on diseases of the circulatory, respiratory, digestive and urinary system and with allergy. Each section contains a list of references to the workers concerned, which in their length indicate that much investigative work was undertaken: the descriptions of the work are however necessarily brief.

EXO-ERYTHROCYTIC SCHIZOGONY IN MALARIA

By P C C GARNHAM, M D, M R C S, D P H

*Reader in Medical Parasitology, London School of Hygiene and Tropical
Medicine (University of London)*

Malaria parasites* undergo four cycles of development (1) the sexual cycle starting with the growth of gametocytes in the vertebrate host and continuing with sporogony in the tissues of the mosquito, (2) the pre-erythrocytic development of the sporozoite, (3) asexual schizogony in the red blood corpuscles and (4) exo-erythrocytic schizogony. The second and fourth stages represent the tissue phases of malaria in the vertebrate host and are the subject of this article. They are still imperfectly differentiated one from another and it is impossible, in many instances, to state where one ends and the other begins. Both phases were unknown until comparatively recently, though GRASSI (1900) in the primary wave of malaria research was forced to the conclusion that there was a third developmental cycle in the body of man, during the incubation period, and that this form would exhibit a special character of its own. He abandoned this opinion when SCHAUDINN apparently demonstrated the direct entry of the sporozoite into the red blood cell.

The theory received little attention for 30 years. JAMES (1931) revived it in order to explain many anomalies in the behaviour of the malaria parasites. He suggested that sporozoites entered connective tissue cells or cells lining the capillary blood vessels and remained there until the cells broke down, 8-10 months later, at the end of the protracted incubation period. RUGE (1936) developed the hypothesis a little further and it was eventually so well supported by accumulating knowledge that there was nearly enough indirect evidence to prove the existence of a tissue phase in human malaria. The evidence included the following points —

1 The chromatin of the sporozoite nucleus is arranged so differently from that of the blood forms that GRASSI (1900) thought that direct development, one from the other, was impossible.

2 Most observers were unable to see the direct penetration of a red blood cell by the sporozoite. [Is there any malarialogist who has not attempted to watch this process under the microscope?]

* The use of the term malaria parasites in this article is confined to blood protozoa belonging to the family Plasmodiidae. Recent work has indicated that some modification will be necessary in the definition of the families and genera in the sub-order Haemosporidiea, and in order to show clearly their relationships a brief account of exo-erythrocytic schizogony in the various genera of the sub-order is included.

3. Quinine has little or no therapeutic action during the incubation period and yet it has a powerful action on the parasites directly they appear in the blood (SERGEANT and SERGEANT 1922).

4. The experiments of FAIRLEY (1945) crystallized the exact nature of the problem. These showed that sporozoites circulated in the blood for about half an hour after inoculation and that they then disappeared. The blood was shown to be non-infectious after this half hour until the end of the incubation period. During this interval in avian malaria (172 hours in the case of *P. cathemerium*) WARREN and COGGESHALL (1937) had already demonstrated that the circulating blood was non-infectious, the parasites being held in the spleen, liver and bone marrow.

Exactly who first saw exo-erythrocytic parasites in malaria will probably never be known. Among the earliest were MACCALLUM (1898) AXENHUTZ (1910) BEN HARIL (1925) and UEGAKI (1930) then HUFF & BLOOM (1935). But the first person to have recognized their significance appears to have been RAFFAELLE (1934). He described unpigmented forms in *P. elongatum* infections and suggested (1933a) that the sporozoites of this species developed within endothelial cells. He also found (1933b) extremely scarce exo-erythrocytic parasites in *P. rodicum* infections in the reticulo-endothelial cells of the liver, spleen and bone marrow of canaries, after inoculation with large doses of sporozoites.

The full significance of these findings was not realized at the time and even after 1937 when JAMES and TATE announced the discovery of the highly characteristic E.E. forms in *P. gallinaceum*, not a few (e.g. HIGHER and WOLFSON 1938a) thought these unpigmented parasites were as likely to be *Toxoplasma* as a stage in the development of *Plasmodium*. Confirmation of JAMES and TATE's work, however, rapidly followed, *P. gallinaceum* proving itself an ideal parasite for the elucidation of the whole cycle in avian malaria. The discovery of pre-erythrocytic forms in the incubation period was announced independently in 1940 by Lily MUDROW and by SHORTT, MEXON and IYER and in 1944 HUFF and COULSTON worked out the full cycle of *P. gallinaceum* in the greatest detail, whilst MUDROW and REICHENOW investigated *P. praecox* (*rodicum*).

Similar stages were seen in many other avian malarial parasites. In 1944 exo-erythrocytic schizogony in saurian malaria was described by THOMSON and HUFF. Finally in 1948 the tissue phase in mammalian malaria was discovered, first in the monkey parasite *P. cynomolgi* (SHORTT and GARNHAM) and slightly later in the human, *P. vivax* (SHORTT, GARNHAM, COVELL and SHUKLA).

Very useful summaries of the subject have been made by GIOVANNOLA (1939) PORTER and HUFF (1940) ELWITT (1940b) and HUFF (1947).

Terminology

New knowledge of the life cycle of the malarial parasites inevitably required an extension of nomenclature. Definitions of the new terms are given below —

Pre-erythrocytic schizogony — This term refers to the development of the sporozoite during the incubation period. It may occupy one generation only, as in mammalian malaria, or several generations, as in the avian form. This stage can be said to terminate on the first appearance of parasites in the red blood corpuscles.

Exo-erythrocytic schizogony — This was the original term employed by JAMES and TATE (1938) to describe the developmental forms they observed in the brain and other organs of chicks infected with *P. gallinaceum*. It was used indiscriminately for early and late forms. It is desirable to confine the use of

the name to stages seen in the post-patent period, i.e., after the parasites have reached the blood

Tissue Phase—This term embraces both pre-erythrocytic and exo-erythrocytic schizogony and is to be used for preference when the exact stage of the infection is unknown

Phanerozoite—Any exo-erythrocytic parasite except pre-erythrocytic forms (HUFF and COULSTON, 1946)

Exo-erythrocytic schizogony *gallinaceum*-type and *elongatum*-type PORTER (1942) made a useful distinction between two types of schizogony. E E development of *gallinaceum*-type occurs predominantly in the lymphoid-macrophage system, including endothelium. E E development of *elongatum*-type is confined to the wandering cells of the blood and organs (particularly the haemopoietic system)

Cryptozoite—HUFF, COULSTON and CANTRELL (1943) devised this word to denote the first stages in the development of the sporozoite. Cryptozoites are the product of the first division of the sporozoite and are contained in a cryptozoic schizont

Metacryptozoite—Following the first cryptozoic generation, are schizonts which produce metacryptozoites and the term (proposed by HUFF and COULSTON, 1944) includes all pre-erythrocytic stages with the exception of cryptozoites

Micromerozoite—Certain E E schizonts consist of many nuclei and little cytoplasm. These microschorizonts eventually produce a large number of micromerozoites (128 or more in the case of *P. relictum*, REICHENOW and MUDROW, 1943). In size and structure they are like the merozoites resulting from schizogony in red blood corpuscles and they are destined to enter such cells themselves

Macromerozoite—The macromerozoites are larger bodies than the micromerozoites; they probably number not more than 64 (in *P. relictum*) within the macroschizont. They do not invade red blood corpuscles, but enter tissue cells

Megaloschizont—This term was applied by HUFF (1942) to describe the large schizonts of *Leucocytozoon* in the tissue cells of the heart, spleen, intestine and liver. The mature forms measure over 100 μ in length and contain thousands of merozoites. They are solid bodies

Merocyst—An analogous structure to the megaloschizont is the merocyst (GARNHAM 1947) of *Hepatocystes kochi*. During the exo-erythrocytic development of this parasite the substance of the schizont becomes highly vacuolated. The vacuoles coalesce in a large internal space and this space is bounded by a thick wall containing innumerable merozoites. The merocyst measures about 2 mm in diameter

Cytomere—WENYON (1926) defines cytomeres as the intermediate bodies of a schizont which actually produce the merozoites. When a certain number of nuclei have formed, the schizont divides into the same number of individual masses, each with a single nucleus. These are the cytomeres; their nuclei undergo further division, and finally merozoites are budded from their surfaces. Such a clear-cut process is rarely seen in the Haemosporididae but various observers have noted the partial differentiation of the schizont during its growth into separate islands or cytomeres. ARAGÃO (1908) first described the phenomenon in *Haemoproteus*. JAMES and TATE (1938) stated that during the growth of *P. gallinaceum* schizonts, the cytoplasm breaks up into a number of cytomeres on the periphery of which the merozoites are developed on digitiform processes. HUFF (1942) showed that during the formation of the megaloschizont of *Leucocytozoon*, the body became divided into numerous (usually several

occurred rarely in the brain. Multiple infections of cells were seen. FANTHAM & PORTER (1944) also found scanty E.E. forms in penguin malaria, which they described under the name of *P. idatum* var. *sphenoides*. MAXWELL (1940) studied a variety of this parasite viz. *P. idatum* var. *minimum*, in canaries. Localization in the brain was common and the presence of large and conspicuous vacuoles in the schizonts was a constant peculiarity in this variety. In tissue culture HAWKING (1946) noted that the merozoites were elongate and sometimes arranged radially around a central core.

MISSIROLI'S (1940) account of the development of the protozoite of *P. raictum* differs from that of the American workers particularly in regard to the primary place of development which Missiroli states is extracellular resulting in the formation of four merozoites. These merozoites are said to enter red blood corpuscles and start the blood cycle.

P. californicum.—This avian parasite is very similar in morphology in all forms to *P. idatum*. Its common E.E. sites are the brain and the liver though in heavy infections unpigmented schizonts may be found in the peripheral blood (in eosinophiles). The early forms have been described by HIXLITZ and MUDROW (1938 and 1939) and were shown to begin as uninucleated parasites lying in endothelial cells or monocytes. These parasites later underwent schizogony dividing into at least 11 merozoites. The late stages have been described incompletely by many authors—HAGGER and WOLFSON (1938a) illustrated what were certainly the E.E. schizonts of this parasite though at that time they were not prepared to differentiate them from *T. phaeosomum*. In length they may measure 32 μ and there may be 100 or more merozoites.

P. circumflexum.—This large parasite of the elongate gametocyte group has been studied by MAXWELL and GOLDSTEIN (1939). E.E. schizonts are found in the following organs (in order of frequency)—lungs, brain, spleen, liver, bone marrow, heart and ovaries. The schizonts reach the size of 3.5 mm in diameter and the merozoites number at least 170. A characteristic feature is the elongate character of the merozoite. The schizonts sometimes show one or more vacuoles, and two kinds occur, one with lightly staining, and the other with much more heavily staining, cytoplasm. They invade the endothelial cells of the cerebral capillaries and the monocytes of other organs. Its erythrocytic stages are unknown.

P. lephurei.—The pre-erythrocytic cycle of *P. lephurei* has been studied by HIFF, COULSTON, LUND and PORTER (1947). Unfortunately the host birds employed by these workers did not appear to be completely suitable for the parasite and many of the E.E. parasites were in an abnormal or degenerated condition. They occur in cells of the lymphoid macrophage system and in fibroblasts and, so far, they have only been recovered from the site of inoculation of the sporozoites in the skin. No constant differences were observed between these pre-erythrocytic forms and those of *P. galinaceum*. In the later stages, exo-erythrocytic parasites are abundant in the capillaries of the brain. Macro- and micro-merozoites were observed by TOSATA and HAWKING (1947) in infected turkeys.

P. lurae.—PERCHASE (1947) and SIMPSON (1944) reported exo-erythrocytic schizogony in this parasite of turkeys. The forms are most numerous in the lungs and brain but also occur in the liver and spleen. In the brain infection is so intense that the capillaries are completely occluded. The exact morphology of these parasites remains unobserved and the pre-erythrocytic stages are unknown.

True Parasitoid of Small Size.—The malarial parasites of birds are conveniently classified into larger and smaller species (RUSSELL WERT and MAXWELL, 1946). Exo-erythrocytic schizogony has been found in few of the smaller species probably because the infections have not been sufficiently

studied BARRETTO (1943) has described, briefly, tissue forms in *P. juxtancleare*. He found them solely in the brain capillaries. The schizonts were elongated structures with 2-19 blocks of chromatin. HEGNER and WOLFSON (1938b) described schizonts in reticulo-endothelial cells from birds infected with *P. nucleophilum*. These infections were apparently mixed with *P. cathemerium* and it seems probable that the schizonts were in reality those of the latter species.

P. elongatum—Exo-erythrocytic schizogony in this species follows a totally different course from that of the parasites described above. RAFFAELE (1934) and HUFF and BLOOM (1935) give detailed descriptions of the development of this species; they demonstrated that schizogony occurred in a wide variety of cells, extending from mature erythrocytes to erythroblasts, haemocytoblasts, plasma cells, macrophages and granulocytes. The overwhelming majority of the parasites occur in the red blood cell series, probably less than 10 per cent in other cells. Except for (a) size and number of merozoites and (b) presence or absence of pigment, there appears to be little difference in the character of the schizont whatever cell it may be inhabiting. The essential difference between *P. elongatum* and the other parasites is the fact that exo-erythrocytic stages of the latter are largely confined to fixed tissue cells, while these stages in *P. elongatum* occur only in wandering cells.

The schizonts of this parasite produce 4-30 elongated merozoites which are arranged in a most characteristic fashion, more like the arrangement seen in schizogony in haemogregarines than in plasmodia. They lie in parallel rows or bundles. Pigment is produced only in the polychromatophil erythroblasts, normoblasts and erythrocytes. In the erythroblasts only a small granule of pigment is produced. There exists, therefore, no clear line of differentiation between exo-erythrocytic and erythrocytic schizogony in this species, and even when the former can be distinguished, it presents features which link it closely with the ordinary schizogony of the blood. Thus, the number of merozoites is small, the cycle of development is short (24 hours), there is no differentiation into macro- and micro-schizonts and, finally, there is the absence of any tendency to invade fixed lymphoid-macrophage tissue.

The complete pre-erythrocytic cycle is still to be described. RAFFAELE (1934) found exo-erythrocytic parasites early in infections before invasion of the peripheral blood had begun and he assumed from this that pre-erythrocytic development occurred in endothelial cells.

Saurian Parasites

Exo-erythrocytic schizogony in American lizards was discovered by THOMPSON and HUFF (1944). It has also been observed by the present reviewer (unpublished work) in the East African skink, *Mabuya maculilabris*.

The cycle in *P. mexicanum* is of considerable interest in that it occurs in both wandering and fixed tissue cells, in other words, it partakes of the characters of both the *gallinaceum*- and the *elongatum*-types of schizogony. The parasites invade basophil erythroblasts, lymphocytes, monocytes, thrombocytes and granulocytes and in such cells the round or oval schizonts produce elongate merozoites, 10 to 40 or more in number. The *gallinaceum*-type of schizogony is seen in reticular cells, endothelial cells of capillaries, littoral cells of the liver and macrophages. There is a strong tendency to invade the true endothelium. In these situations, the schizonts are larger and contain 72 or more round merozoites.

Mammalian Parasites

Reports claiming the discovery of exo-erythrocytic schizogony in human or monkey malaria have appeared from time to time and there can scarcely be a single worker in this field who has not thought at one time or another that he

has at last found the cryptic forms. Usually on reflection and re-examination, it has been possible to find an alternative explanation, but some claims were put forward and their unreliability has recently been analysed by ANGELINI (1947). Other workers have described various intracellular bodies, but have regarded them more conservatively (e.g. DECOURT and SCHNEIDER 1938; DUBIN 1947). When the liver schizonts of *P. cynomolgi* were ultimately discovered (SHORTT, GARNHAM and MALAMOS 1948) their morphology was so entirely unequivocal that they received instant acceptance and the long search at last came to an end. So far the exo-erythrocytic forms have only been demonstrated in *P. cynomolgi* and *P. vivax*. Recent discoveries in other mammals refer to parasites incorrectly placed in the family Plasmodiidae: they are mentioned briefly later in this article.

The technique leading to the discovery of these forms was as follows. In the monkey it involved the introduction of hundreds of thousands of sporozoites by bite and by the inoculation either of large numbers of the whole mosquitoes intraperitoneally or of the salivary glands intravenously. Seven days later the animal was sacrificed and specimens were taken from every organ and tissue. Sections were stained and examined and the schizonts were eventually found in the liver material. After this, it was an easy matter to repeat the experiment in man with *P. vivax* and to extract the necessary tissue by liver biopsy.

P. cynomolgi.—Pre-erythrocytic schizogony of this species has been described by SHORTT and GARNHAM (1948b) and by HAWKING, PERRY and THURSTON (1948). The process takes place in the parenchymatous cells of the liver and probably only one generation is involved. The earliest forms were seen on the fifth day after infection. They are spherical or ovoid bodies about 10μ across and contain about 50 pieces of irregularly shaped chromatin lying throughout the granular cytoplasm. A characteristic of this stage is the sharply cut margin of the parasite. Growth continues and maturity is reached about the eighth or ninth day. During this time a few curious vacuoles develop in the parasite and indentations of the periphery occur sometimes resulting in the formation of one or more lobose arms. Nuclear multiplication continues and eventually nearly a thousand merozoites are formed. Each merozoite consists of a small fragment of chromatin on one side and a fairly dense piece of cytoplasm on the other giving the appearance of a "solid ring," a little over 1μ in diameter. The mature schizont itself measures about 35μ in diameter. Exceptionally forms as large as 60μ are to be seen.

After the rupture of the schizont and the escape of the merozoites into the sinusoids, invasion of the residual mass by phagocytes occurs. These cells are lymphoid-macrophage cells, plasma cells and polymorphonuclear leucocytes.

Persistence of the tissue cycle in the liver parenchyma has recently been demonstrated by SHORTT and GARNHAM (1948c). Schizonts were found 3½ months after the original sporozoite-induced infection and after months' latency when parasites were absent from the peripheral blood. Schizonts were extremely rare—they resembled pre-erythrocytic forms in most respects, a possible difference being that the younger (5-day-old) parasites appeared to possess a well defined, very limiting membrane. There is little doubt that these schizonts represent the tissue forms. They presumably continue to develop in the liver throughout an infection, producing showers of merozoites which, however, are normally destroyed by the immune mechanism. Something upsets immunity—the merozoites are then able to continue the erythrocytic cycle and relapse ensues.

P. vivax.—The E.E. schizonts of this species resemble those of *P. cynomolgi* very closely. Ovoid plasmodial masses develop within the parenchymatous cells of the liver. These exhibit vacuole indentation of periphery and

nuclear multiplication, resulting in the formation by the seventh day of a fully mature schizont with 800–1,000 merozoites. The size of the schizont is, perhaps, rather larger than in *P. cynomolgi*, about $42\ \mu$ in diameter.

Exo-erythrocytic Schizogony in the Haemoproteidae

The following genera are recognized in this family, *Haemoproteus*, *Leucocytozoon* and *Hepaticystes*. It is probable that the family will have to be widened to include the malarial parasites of the bat, flying fox, sitatunga and other mammals, these also are considered briefly in this section. All the members of this family exhibit gametocytes only in the blood stream. The Haemoproteidae show affinities not only with the Plasmodiidae but with various genera in the Theileriidae. "Koch's blue bodies" of *Theileria parva* bear a strong resemblance to the E E forms of avian plasmodia and halteridia, and the cycle of the newly described piroplasm, *Cytauxzoon sylvicaprae* NEITZ and THOMAS (1948) of the Duker shows an even closer relationship.

Haemoproteus was shown by ARAGÃO (1908) to undergo a tissue phase in the endothelial cells of the blood vessels of the lungs and other organs of the body. Segmentation into cytomeres occurs, each of these continues to grow and eventually enormous numbers of merozoites are produced, enclosed by fine cyst walls. These forms reach $60\ \mu$ in diameter, and smears show that the cytoplasm has a meshed structure with fairly numerous vacuoles and many nuclei. WENYON (1926) noted that cytomere formation was not inevitable but that the schizont—a large sausage-shaped body—might give rise directly to merozoites. These schizonts may collect in groups in the organs, e.g., liver or spleen, separated from each other by walls of indeterminate origin, the whole focus measuring several hundred microns in diameter.

Leucocytozoon E E schizonts were described by HUFF (1942). Two types were found, one occurring in parenchymatous cells of the liver, causing little alteration in the cell, and the second, the megaloschizont, in the heart, liver, spleen and intestine. The megaloschizonts are formed from numerous cytomeres which eventually give rise to extremely numerous bacilloid merozoites, arranged without order in the schizont. These forms may be as long as $105\ \mu$. It is probable that the megaloschizont develops within macrophages and also in cardiac muscle cells. These cells become enormously hypertrophied and the nuclei also enlarge.

Hepaticystes kochi (a parasite of the lower African monkeys) has recently been studied by GARNHAM (1948) and details of its exo-erythrocytic cycle were elucidated. Development proceeds in the parenchymatous cells of the liver, first as a minute round body, then as a sphere with peripheral nuclei, the nuclei later multiply and become scattered throughout the cytoplasm. The surface of the parasite shows multiple invaginations, vacuolation occurs and the fluid accumulates in a large central vacuole which expands to form the merocyst. Further division of the nuclei has continued in the meantime, possibly with the formation of cytomeres. Eventually the merozoites collect in enormous numbers in the wall of the merocyst, which ruptures and the majority of the merozoites escape into the circulation where they grow into gametocytes. The mature merocyst measures up to 2 mm in diameter. These E E forms persist throughout the infection, discharging a stream of gametocytes into the blood.

A similar parasite has recently been described by RAY (1948) from the Himalayan flying squirrel. It has an E E cycle in the liver resembling in many ways that of *H. kochi* though the cysts are multiple.

Malarial Parasites of Bats—MER and GOLDBLUM (1947) found that the bats (*Myotis myotis* and other species) of Palestine, harboured a blood parasite which underwent intense schizogony in the reticular cells and the granulocytes of the

bone marrow. E.E. forms were also present in the wandering and fixed macrophages of the lung, kidney and liver. The parasites in the liver measure little more than 8μ in diameter. They are of course unsegmented and they produce a relatively small number of merozoites. Ectoparasites of the family Nycteribiidae infest these bats and it is claimed that the glands of one fly contained sporozoites.

Another interesting parasite of bats (the fruit bat—*Pteropus Gouldi*) was studied by MAXWELL (1946) in New Guinea. In addition to gametocytes he found a fair number of unsegmented schizonts in the peripheral blood and these schizonts were all extracellular. They contained a variable number of merozoites and were said to resemble the E.E. forms of avian malaria. It is possible that these bodies in reality were detached portions of a rupturing merozoite. They are not unlike the structures which SCHWARTZ (1933) described from the peripheral blood and bone-marrow in *H. lachrymans* infections. It is doubtful whether they should be regarded as the mammalian equivalent of *P. elongatum* because although in the blood, they lie free and are not in cells of the haemopoietic system.

Biological Significance of E.E. Schizogony

The conclusion that E.E. schizogony was an essential part of the life cycle of malaria parasites was accepted by most workers after the early work of James and others. Because of its erratic and cryptic nature however some people at first were unwilling to accept this interpretation and they put forward several theories. BRUNST (1937) suggested that the phenomenon might represent an accidental histotropism caused by the unfavourable action of the blood on certain merozoites escaping from the ordinary blood schizonts. CHORTIS (1938) thought that E.E. schizogony was not a normal developmental stage but appeared as the result of loss of function of the reticulo-endothelial cells. These cells start phagocytosis of the parasites but are unable to complete the process and the parasites then continue their own development. CORRAVERTS as late as 1941 regarded the presence of E.E. forms as a sort of accident in the life history of malarial parasites, occurring in only a few species. He also thought that development in histiocytes was not undergone in sporozoites. The same worker (1942) stated that the extent of the process depended upon the degree of balance between host and parasite—in other words upon immunity. His experiments had shown that when sporozoites or suspensions of tissues containing E.E. forms were inoculated into clean birds E.E. forms rarely appeared—because there was no immunity. If however the inoculation was made into birds in the latent phase of a homologous infection no E.E. forms appeared.

Further knowledge particularly in regard to the tissue phase in mammalian malaria, has made it clear that exo-erythrocytic schizogony is a normal part of the cycle of practically all the malaria parasites just as it is in all members of the Haemosporididae. Variation in incidence or extent of the tissue phase is no greater than similar fluctuation in the number for instance of gametocytes, and as is well known, certain strains of parasites can become unbridled and permanently gametocyte free. It is now clear that the sporozoite inoculation proceeds to certain sites the exact location of which depends on the species and there develops through one or more generations the schizont which produces blood infection, merozoites. These may persist in the original site or elsewhere in the body or they may migrate. It is generally agreed that in the tissue phase the inoculated parasites develop into gametocytes. In some species the gametocytes may develop directly from blood schizonts of

HAWKING *et al* (1948) go as far as to speculate on the phylogenetic relations between the malaria parasites and allied protozoa belonging to the Eimeriidea, based on their common development in intestinal epithelium (*e g*, *Schellackia*) or in hepatic epithelium which is embryologically derived from the former (*e g*, *P. cynomolgi*, *H. kochi*)

There are still many gaps in our knowledge of E E schizogony. The morphology of this stage is incompletely described, although novel methods have been devised to study it. SHORTT, MENON and IYER (1940) used inoculation into the chorio-allantois of the fowl embryo to observe *P. gallinaceum* infections, HAWKING (1944) and more recently GRAMICCIA and BLACK (1948) have employed tissue culture as a means of studying E E forms. The behaviour also of these parasites is only partly understood. E E forms are present in some strains of a species and yet may be completely absent throughout hundreds of passages in another, as HEWITT (1940a) found in *P. cathemerrum*. On the other hand, growth in tissue culture may produce a strain which results in infections of an exclusively exo-erythrocytic nature, this peculiarity being maintained unchanged through many subsequent passages (LEWERT, 1948). The development of E E stages in different hosts has been studied by HUFF, COULSTON, LAIRD and PORTER (1947), they showed that *P. lophurae* exhibited most numerous E E forms in young turkeys, pheasants and canaries, but few in guinea fowls, on the other hand, pre-erythrocytic forms were commonest in guinea fowls and less common and more abnormal in morphology in chickens, turkeys and ducks.

The infectivity on sub-inoculation of organs containing pre-erythrocytic parasites shows certain peculiarities which at present are not understood. In avian malaria, subinoculation is always successful, in mammalian, it never is. In this respect, the mammalian plasmodia behave like the Haemoproteidae whose asexual stages are only slightly infective (COATNEY, 1933). The failure to infect may be due to the localization of the parasites in special cells (*e g*, hepatic parenchyma rather than undifferentiated endothelium) or it may be because there is probably only a single and lengthy cryptozoite stage in mammalian malaria, with no free merozoites until the end of the incubation period. The chemotherapeutic action of drugs is likely to show corresponding variations based partly on this fundamental difference between the various species. A discussion on this subject is beyond the scope of the present review.

For a long time past, people have felt the need for a reclassification of the malaria parasites. MISSIROLI (1937) suggested the creation of a new genus *Istiocytozoon* for the two avian parasites *P. elongatum* and *P. gallinaceum*, based on their evolution in reticulo-endothelial cells. This has subsequently proved to be an unsatisfactory basis and the name has been unacceptable to the majority of workers. CORRADETTI (1938) took the opposite view and suggested fusing the two families Plasmodiidae and Haemoproteidae, because the distinction is a purely physiological one referring to the type of host cell parasitized. This interpretation would appear to be invalid because there are gross morphological differences and also, as PORTER and HUFF (1940) pointed out, the two families have distinctive invertebrate hosts. The present position is well summarized by GRAMICCIA (1948) in the statement that a revision of the sub-order Haemosporididae is necessary but cannot be made until many obscure points in the biology and life history of the more important parasites are cleared up. In the reviewer's opinion, taxonomic changes should be postponed until the nature of the tissue phase has been elucidated in (a) *P. falciparum* or *P. reichenowi*, (b) the small avian plasmodia (*e g*, *P. rouxi*), (c) the mammalian analogue of *P. elongatum* (possibly the plasmodium of the New Guinea flying fox), and (d) probably certain novelties such as the virulent haemotozoon (*P. berghiei*) of the Congo tree rat (VINCKE and LIPS, 1948) and

bone-marrow. E.E. forms were also present in the wandering and fixed macrophages of the lung, kidney and liver. The parasites in the liver measure little more than 8μ in diameter. They are of course unpigmented and they produce a relatively small number of merozoites. Ectoparasites of the family Nycteribulidae infest these bats and it is claimed that the glands of one fly contained parozoites.

Another interesting parasite of bats (the fruit bat—*Pteropus Gouldi*) was studied by Maxwell (1948) in New Guinea. In addition to gametocytes, he found a fair number of unpigmented schizonts in the peripheral blood and these schizonts were all extracellular. They contained a variable number of merozoites and were said to resemble the E.E. forms of human malaria. It is possible that these bodies in reality were detached portions of a rupturing macrocyt. They are not unlike the structures which SCHWARTZ (1933) described from the peripheral blood and bone marrow in *H. Locke* infections. It is doubtful whether they should be regarded as the mammalian equivalent of *P. elongatum* because although in the blood, they lie free and are not in cells of the haemopoietic system.

Biological Significance of E.E. Schizogony

The conclusion that E.E. schizogony was an essential part of the life cycle of malaria parasites was accepted by most workers after the early work of James and others. Because of its erratic and cryptic nature, however, some people at first were unwilling to accept this interpretation and they put forward several others. BARNETT (1937) suggested that the phenomenon might represent an accidental histotrophism caused by the unfavorable action of the blood on certain merozoites escaping from the ordinary blood schizonts. ENORTIS (1938) thought that E.E. schizogony was not a normal developmental stage but appeared as the result of a loss of function of the reticulo-endothelial cells. These cells start phagocytosis of the parasites but are unable to complete the process and the parasites then continue their own development. CORRADOTTI as late as 1941 regarded the presence of E.E. forms as a sort of accident in the life history of malarial parasites, occurring in only a few species. He also thought that development in histiocytes was not undergone by parozoites. The same worker (1947) stated that the extent of the process depended upon the degree of balance between host and parasite—in other words, upon immunity. His experiments had shown that when sporozoites or suspensions of tissues containing E.E. forms were inoculated into clean birds, E.E. forms readily appeared—because there was no immunity. If, however, the inoculation was made into birds in the latent phase of a homologous infection, no E.E. form appeared.

Further knowledge, particularly in regard to the tissue phase in mammalian malaria, has made it clear that exo-erythrocytic schizogony is fundamental part of the cycle of probably all the malaria parasites, just as it is in other members of the Haemosporidia. Variations in incidence occur but there are no greater than similar fluctuations in the number for instance of gametocytes, and as is well known certain strains of parasites can become completely and permanently gametocyte-free. It is now clear that the parasite on inoculation proceeds to a certain site the actual location of which depends upon the species, and there develops through one or more generations into a schizont which produces blood infecting merozoites. Tissue forms may persist in this organism or else live in the body or they may be so evanescent that after the incubation period, they disappear entirely. With certain species, exo-erythrocytic forms may develop as CORRADOTTI (1941) and others have shown, directly from blood schizonts even from the inoculation of single trophozoites.

HAWKING *et al* (1948) go as far as to speculate on the phylogenetic relations between the malaria parasites and allied protozoa belonging to the Eimeriidea, based on their common development in intestinal epithelium (*e.g.*, *Schellackia*) or in hepatic epithelium which is embryologically derived from the former (*e.g.*, *P. cynomolgi*, *H. kochi*)

There are still many gaps in our knowledge of E E schizogony. The morphology of this stage is incompletely described, although novel methods have been devised to study it. SHORTT, MENON and IYER (1940) used inoculation into the chorio-allantois of the fowl embryo to observe *P. gallinaceum* infections, HAWKING (1944) and more recently GRAMICCIA and BLACK (1948) have employed tissue culture as a means of studying E E forms. The behaviour also of these parasites is only partly understood. E E forms are present in some strains of a species and yet may be completely absent throughout hundreds of passages in another, as HEWITT (1940a) found in *P. cathemerium*. On the other hand, growth in tissue culture may produce a strain which results in infections of an exclusively exo-erythrocytic nature, this peculiarity being maintained unchanged through many subsequent passages (LEWERT, 1948). The development of E E stages in different hosts has been studied by HUFF, COULSTON, LAIRD and PORTER (1947), they showed that *P. lophurae* exhibited most numerous E E forms in young turkeys, pheasants and canaries, but few in guinea fowls, on the other hand, pre-erythrocytic forms were commonest in guinea fowls and less common and more abnormal in morphology in chickens, turkeys and ducks.

The infectivity on sub-inoculation of organs containing pre erythrocytic parasites shows certain peculiarities which at present are not understood. In avian malaria, subinoculation is always successful, in mammalian, it never is. In this respect, the mammalian plasmodia behave like the Haemoproteidae whose asexual stages are only slightly infective (COATNEY, 1933). The failure to infect may be due to the localization of the parasites in special cells (*e.g.*, hepatic parenchyma rather than undifferentiated endothelium) or it may be because there is probably only a single and lengthy cryptozoite stage in mammalian malaria, with no free merozoites until the end of the incubation period. The chemotherapeutic action of drugs is likely to show corresponding variations based partly on this fundamental difference between the various species. A discussion on this subject is beyond the scope of the present review.

For a long time past, people have felt the need for a reclassification of the malaria parasites. MISSIROLI (1937) suggested the creation of a new genus *Istiocytozoon* for the two avian parasites *P. elongatum* and *P. gallinaceum*, based on their evolution in reticulo endothelial cells. This has subsequently proved to be an unsatisfactory basis and the name has been unacceptable to the majority of workers. CORRADETTI (1938) took the opposite view and suggested fusing the two families Plasmodiidae and Haemoproteidae, because the distinction is a purely physiological one, referring to the type of host cell parasitized. This interpretation would appear to be invalid because there are gross morphological differences and also, as PORTER and HUFF (1940) pointed out, the two families have distinctive invertebrate hosts. The present position is well summarized by GRAMICCIA (1948) in the statement that a revision of the sub-order Haemosporidieae is necessary but cannot be made until many obscure points in the biology and life history of the more important parasites are cleared up. In the reviewer's opinion, taxonomic changes should be postponed until the nature of the tissue phase has been elucidated in (a) *P. falci-parum* or *P. reichenowi*, (b) the small avian plasmodia (*e.g.*, *P. rouxi*), (c) the mammalian analogue of *P. elongatum* (possibly the plasmodium of the New Guinea flying fox), and (d) probably certain novelties such as haemotozoon (*P. berghei*) of the Congo tree rat (VINCKE and

the plasmodia of the Canadian bull frogs (FANTHAM PORTER and RICHARDSON 1947) *P. knowlesi* might be added to this list because of certain peculiarities, e.g. its short cycle (74 hours) and its apparent non-transmissibility by mosquitoes. A basis for classification is indicated in the table below which shows tentatively the position of the more important genera and species.

| Size of E E Schizonts | Location of E.E. Schizogony | HAEMOPROTEIDAE | PLASMODIIDAE |
|--------------------------|--------------------------------|--|--|
| | | Gametocytes only in Blood In vertebrate Host not a Mosquito | Gametocytes and Schizonts in Blood Invertebrate Host a Mosquito |
| Macroscopic or nearly so | Endothelium of blood vessels | <i>Haemoproteus</i> | + |
| | Liver heart, kidney parenchyma | <i>Leucosporicon</i> | + |
| | Liver parenchyma | <i>H. polycystis</i> | <i>Plasmodium vivax</i> (synonym) |
| Microscopic | Reticulo-endothelium | <i>Plasmodium</i> sp. of Palestine bats | <i>Plasmodium gallinaceum</i> , <i>lurum</i> etc. |
| | Haemopoietic system | <i>Plasmodium</i> sp. of New Guinea flying fox | <i>Plasmodium elongatum</i> |
| | R.E. and haemopoietic system | + | <i>Plasmodium meikani</i> |

Re-classification may be required.
+ Gaps to be filled.

in ampoules are said to keep indefinitely, and can be used with confidence for making suspensions

In a study of 1,084 strains of *Proteus* in areas free from human rickettsial diseases, WINKLE (p 573) found 12 serological types, including 4 that behaved like X2, X19, XU, and XK The same author (p 574) isolated two strains of *Proteus* X19, one from the blood and one from the urine, of patients with (or suspected of) typhus

WISHART and MALCOMSON (p 194) show that *R prowazeki* and *R mooseri* possess type-specific antigens labile at 60°C, and a common antigen stable at 100°C but destroyed at 120°C The latter contains two factors, one of which is common to *Proteus* OX19 The Weil-Felix reaction, therefore, is a specific immunological reaction BENDICH and CHARGAFF (p 407) have extracted two antigenic fractions from *Proteus* OX19, one of which shows specificity with typhus sera and with *Proteus* antisera, the other with the latter only

The Pan-American Typhus Commission (p 703) have adopted as standard the Castañeda *Proteus* OX19 antigen

SIEVERS (p 890) uses living *Proteus* OX19 for the Weil-Felix test

A rapid slide test for typhus, in which serum and an emulsion of *Proteus* OX19 are used, is described by SANTO, readings are made within 12 minutes

For use in agglutination tests, SHEPARD and TOPPING (p 573) describe a method of preparing rickettsial suspensions from infected yolk sacs, which entails washing the rickettsiae, centrifugation, and absorption of much of the remaining yolk-sac material with Celte The method was satisfactory with the rickettsiae of epidemic and murine typhus, and Rocky Mountain fever, less so with Q fever and not at all with scrub typhus

GIROUD and JADIN (p 891) have used the rickettsia-agglutination test with epidemic and murine antigens, in epidemic typhus Homologous agglutination is at first no greater than heterologous, but becomes so at a later stage HAMMARSTRÖM *et al* (p 194) have found the rickettsia-agglutination test more sensitive and reliable than the Weil-Felix in typhus They describe the technique used, even the slightest microscopical clumping was regarded as positive In tests on refugees to Sweden from German concentration camps, in whom typhus occurred, HAMMARSTRÖM *et al* (p 652) found that the rickettsia agglutination test gave positive results about the 5th day of disease, but the Weil-Felix only about the 9th day The former, therefore, appears to be the more reliable in diagnosis

PACKALÉN (p 809) prefers the complement-fixation test to the rickettsia-agglutination test because of the difficulty of the Hammarström technique BERTSON (p 302) has shown that with the complement-fixation reaction, epidemic and endemic (murine) rickettsiae can be differentiated because the reaction with homologous strains is at a higher titre than reactions with heterologous strains She used 16 epidemic and 3 endemic strains in these tests, and the corresponding sera from convalescent guineapigs In comment, MEGAW points out that the margin of difference is not great MALCOMSON and WISHART (p 407) have been able to differentiate epidemic and murine typhus by means of the complement-fixation test in which type-specific antigens are used the titres being 2-4 times as high with homologous as with heterologous antigens The same authors (p 408) have written on the serology of typhus, but for details the original should be consulted

The quantitative complement-fixation test for typhus was used experimentally by VARLEY and WEEDON (p 654), who used various epidemic and murine antigens and guineapig antisera Although titres were high when homologous antigens and antisera were used there were some results which indicated that the test is not always type-specific in that one murine antiserum did not give high titres with all the murine antigens

GROUD and JUDE (p. 1057) have found that the complement fixation reaction is more sensitive than the Weil-Felix in giving positive results in persons inoculated with rabbit lung epidemic vaccine.

Clinical findings treatment.—The clinical features observed in 244 cases of typhus in middle Europe during the war are recorded by LACHNITZ (p. 94). The incubation period was never less than 12 days. The liver was usually enlarged. An early leucopenia was followed by moderate leucocytosis. In many cases there were casts and red cells in the urine.

GROUD (p. 711) sets out the reasons why he thinks that inapparent and latent infections play a part in the epidemiology of typhus, and gives examples of the isolation of rickettsiae from apparently healthy persons. He regards the rickettsia-agglutination test as more reliable than the Weil-Felix. JUDE and BALMER (p. 811) report two cases in which injection of gonococcus vaccine apparently lighted up latent typhus infections which had probably been present for some time. They suggest that such latent infection may play a part in the carry-over of infection from one epidemic to another.

HEIDE (p. 193) claims to have demonstrated rickettsiae in blood smears of patients with louse-borne typhus.

NORVIT (p. 632) states that electrocardiographic readings show abnormalities in most cases of typhus but thinks that extracardiac factors must play an important part in producing them.

VAN DEN ENDE *et al.* (p. 477) have written a substantial monograph on chemotherapeutic and other studies of typhus, in which they describe tests on 238 substances in animals, and trials in man of the two most favorable compounds. The results in man were not encouraging. The monograph also contains chapters on vaccine preparation (murine type in mouse lungs) and on the antigenic structure of epidemic and murine rickettsiae. These differ sufficiently to be regarded as distinct species but they contain antigens which are heat labile and which are not specific, as well as those which are specific.

HAAG (p. 892) strongly believes that full doses of streptomycin, and of intravenous calcium given as early as possible are of great value in typhus.

MURRAY *et al.* (p. 608) show that streptomycin has only slight inhibitory effect when administered into yolk sacs of embryo chicks shortly before inoculation with *R. prostratus* less with *R. mooseri* and none with *R. vivax*. They think that it is unlikely to be useful in these rickettsial infections in man.

Vaccination.—FERNICHI OV and RAJNER (p. 633) have devised a new method of preparing the Weil vaccine, which is of feeding lice on a mixture of defibrinated blood and triturated bodies of infected lice through a membrane of skin from fresh human cadavers.

CARASSO (p. 809) having shown that guinea pig blood is not toxic for human lice (as is generally thought) but that lice cannot digest it points out that they may be fed on guinea pigs infected with *R. prostratus* and subsequently on immune human beings, and that they thus develop murine infection. This method of infecting lice has advantages over the Weil-rectal method. WRIT (p. 1056) has found during the war in Poland that the louse intestine vaccine was much more effective than the mouse lung and yolk sac vaccines. He thinks that *R. prostratus* maintained in mice steadily approaches the murine type and that vaccines of murine type do not protect against louse typhus. MORING (p. 1058) shows that in mice inoculated with the Weil vaccine the response to the rickettsia agglutination test and the protection afforded are according to the dose of vaccine given. STIEBER (p. 861) thinks that skin reactions to the Weil vaccine in persons who have previously received it are probably due to serum in the albumin from the bodies of the lice used.

The epidemic typhus in use of the U.S. Arm was very serious, even causing death, but the low incidence of the disease in Europe was due largely to M.L.

or DDT powders SADUSK (p 811) shows that the ether-treated yolk-sac vaccine of the Breinl strain given in 3 (later 2) doses at intervals of 7-10 days, with refresher doses every 6 months (later at the beginning and middle of the typhus season) protected against epidemic, but not against murine infection GILLIAM (p 408) in Egypt showed that one or two doses of Cox vaccine had some effect in reducing the severity of typhus subsequently acquired, but little in prevention, three doses, however, did reduce the attack rate BERKE (p 512) used the Cox vaccine with some success in Afghanistan

GROUPE *et al* (p 197) describe the methods they used to increase the yield and potency of typhus vaccines prepared from infected yolk sacs, but for details the original should be consulted BERKOWITZ (p 513) has increased the yield of yolk-sac cultures of epidemic and murine rickettsiae by inoculating with a small dose on the 7th day, which allows the embryo to live 11 days longer, when a good growth is obtained

HAAGEN and CRODEL (p 196) describe a dried vaccine of yolk-sac cultures of murine and epidemic rickettsiae which, although not suitable for general use, had anti-infectious properties when tested in man (in Germany during the war), in that it apparently was effective against subsequent attempts at virulent infection

FAJERSTEIN and BESDENJESZNICH (p 409) found that vaccination with 3 doses gave definite though not complete protection against typhus in Russian railway workers, and that after the course had been repeated in successive years the rate of protection increased

SADUSK and KUHLENBECK (p 196) refer to an outbreak of illness after the use of live bile-attenuated typhus vaccine in Japan, and emphasize the risks of such a vaccine In comment, however, MEGAW remarks on the good results achieved in French North Africa with this kind of vaccine

FLECK (p 1057) has obtained from the urine of patients with typhus, a substance which, when injected into guineapigs, protects against the disease and produces positive reactions to the Weil-Felix reaction He used this substance as a vaccine in man during the German occupation of Poland

Control—SOPER *et al* (p 892) describe the use of louse powders (MYL and DDT) in the control of outbreaks of typhus in Italy during 1943-45 These outbreaks have been referred to several times in this *Bulletin*, but the present authors give much detail of procedure, which should be sought in the original GEAR and MURRAY (p 702) state that outbreaks of louse typhus occur almost every year in the Africans of the Eastern Transvaal, but whereas control was formerly difficult, the use of DDT is now likely to eradicate the disease A rapid slide test has been found useful in detecting the nature of an outbreak MUSGRAVE (p 58) tested the lethal capacity to lice of garments impregnated with DDT in various proportions Shirts holding 0.2 per cent of their weight of DDT were effective, the DDT persists at high temperatures and the chief loss of insecticidal power is due to loss of impregnated fibres from the surface of the cloth

Flea typhus

Epidemiology—MOOSER (p 191) has reviewed the research work of 20 years on the relationship between murine and classical typhus

POLLARD *et al* (p 574) gave, by mouth, large doses of a saline suspension of yolk-sac material infected with murine typhus, to 6 healthy volunteers, of whom one became ill with a typical attack They think that consumption of food contaminated by infected flea faeces, or rat urine, may be the cause of some cases of this disease, but in comment MEGAW suggests that in view of the large dose given in the experiment, the occurrence of this form of infection in nature is probably rare

CODERONOTI (p. 302) claims to have isolated a murine strain of rickettsiae for the first time in Ethiopia. By subinoculation in lice and guinea-pigs the strain showed a tendency to develop characteristics of the epidemic type.

KATZAL (p. 893) states that it is now well known that human typhus in Shanghai is of murine origin. He performed the Weil-Felix reaction on the sera of rats for several years, and the percentage positive (1 in 100) fell from 10.3 in 1942 to 2.3 in 1945. There was a comparable fall in the number of positive reactions in human sera. In a fuller version of the same paper (p. 1089) he makes the point he has often stressed, that murine rickettsiae can adapt themselves, under exceptional circumstances, to transmission by human lice. Louse-borne epidemics in Shanghai tend to become arrested in hot weather. LEE (p. 574) found rickettsiae in fleas from rats trapped in a poorhouse in Perpignan, during an outbreak of typhus. A large proportion of the rats (*R. norvegicus*) showed positive Weil-Felix reaction. He also isolated rickettsiae from the mite *Liponyssus bacoti* found on the rats, but he thinks that fleas are the chief if not the only vectors.

WILEY (p. 199) thinks that typhus of murine origin is much more prevalent in the United States than the reported figures indicate. In the north it is found only in business areas of towns, but in the south cases also occur in rural districts. For control DDT, calcium cyanide, sodium fluoroacetate and AITL are all useful. The incidence rate of flea-borne typhus in part of Alabama was 4.28 per 100,000 in 1943, and HILL and LUGANAN (p. 881) show that it was about the same in rural as in urban localities, infection being obviously associated with dusty work in rat-infested places. BLACK *et al.* (p. 885) discuss the incidence of typhus of murine type in California since 1916.

RUIZ-SANCHEZ *et al.* (p. 304) found positive Weil-Felix tests in 18 per cent of apparently healthy persons in part of Mexico, where murine typhus is common.

POWERS LEBRON *et al.* (p. 186) found positive complement-fixation reaction (with an epidemic type antigen) in about half the rats examined in Porto Rico, but the Weil-Felix reaction was positive in only a small proportion. Typhus of murine origin is common in the area.

Tests.—Using the Fitzpatrick slide technique [this Bulletin 1945 v. 4, 1952] NELSON (p. 703) has found the rickettsia-agglutination test "also for differentiating murine from epidemic typhus and Rocky Mountain fever" result not always obtained with other techniques. This test was more specific than the Weil-Felix and became positive earlier than the complement-fixation reaction in the 22 cases of murine typhus tested.

POLLARD *et al.* (p. 303) have devised a test in which the larvae of *Deas* infected with murine typhus are used for complement fixation with homologous murine sera. This procedure is a rapid method of detecting the infection in the flea.

Treatment.—DÍAZ RIVERA *et al.* (p. 189) report decided benefit from *p*-aminobenzoic acid in the treatment of a few cases of murine typhus. Methylene blue, either by subcutaneous injection or by the mouth, was found useful in the treatment of mice infected with *R. mooseri* and HIKETH and SCHILLING (p. 184) think that it is worth trial in man.

Vaccination. Control etc.—OX (p. 59) describes the method of preparation of murine vaccine carried out at the Hadassah Institution, Jerusalem.

Fleas and other ectoparasites of rats can be well controlled by using DDT (10 per cent powder) in their burrows, but complete elimination is not achieved (LEWIS and NICKOLSON, p. 574). On the other hand if DDT is thoroughly and carefully applied to the haunts of rats the number of fleas can be reduced almost to zero. DILLIS (p. 705) reaches this conclusion as a result of work on murine typhus control in Texas. In an account of measures taken in part of Texas to control typhus of murine origin COO (p. 188) shows that by dusting rat runs with DDT reduction in the incidence was achieved, and that good

results were obtained against the rats themselves by the use of sodium fluoroacetate. The significance of the complement-fixation test in rats is thought to be doubtful. Instructions for the destruction of rats and their fleas, as a measure of control of murine typhus and plague, are given by ELISHWITZ (p 1064), who uses DDT and the rat poisons ANIU and sodium fluoroacetate.

Proctus OXK type vector mite

Epidemiology transmission—KALRA (p 575) quotes figures which indicate that mite, flea and tick typhus are widely distributed in India, and that the mite-borne disease is especially prevalent in Bengal, Assam and Madras. *R. orientalis* has been recovered from *Trombicula deliensis* mites which are abundant at 7,000 feet in the Kumaon Hills. AUDY (p 577) noted that the differences observed in various parts of Assam in the risk of infection of troops with scrub typhus were correlated with the presence or absence of *T. deliensis*. These mites could be taken to indicate the movements of rats and by trapping rats an impression of the presence of mites could be obtained.

BRUNEAU and NGUYEN-DINH-DIEP (p 655) report an outbreak of scrub typhus in a garrison of a fort in Indo China. All the 16 cases occurred in the 139 Annamite soldiers; none in the 90 French, the freedom of the latter may have been the result of immunity due to previous contact with the infection. A few cases of scrub typhus were reported in American troops in China but it is not known how widespread the disease is. MILLSPLUGH and FULLER (p 705) have found *Trombicula deliensis* on various mammals and birds in Yunnan and Kweichow provinces and this appears to be the first record of this mite from China.

PHILIP (p 989) studied scrub typhus in part of Japan where it has been endemic for many years, but where the incidence is falling. Complement-fixation tests with different strains of *R. orientalis* gave very diverse results with the same sera, a point to bear in mind. He (p 990) has written on the identification of the mites of voles in Japan.

In Dutch New Guinea GRIFFITHS (p 1060) studied rats and their mites in various locations. There was no evidence that the rats (*R. concolor* group) were infected with scrub typhus in the rain forest, but abandoned village and garden areas, and beach and forest margins were definitely associated with transmission of the disease. *Trombicula deliensis* was the common mite.

PHILIP and WOODWARD (p 305) report their observations on the *Trombiculid* mites of the Philippines.

JOHNSON (p 200) states that there is strong evidence that *Rattus praetor* played a part in the epidemiology of scrub typhus in the Solomon Islands during the war.

Aetiology—GIROUD (p 304) has studied the relationship between morphological appearance and pathogenic properties of two strains of scrub typhus rickettsiae.

SMADAL *et al* (p 513) have found a toxin lethal to mice in yolk-sac cultures of the Gilliam strain of *R. orientalis*, which can be neutralized by highly diluted homologous antisera. Certain other strains did not produce a toxin.

DIERCKS and TIBBS (p 894) found that the best results for staining *R. orientalis* are given by MacNeal's tetrachrome stain, they give details for its use.

Pathology—In a study of the pathology of scrub typhus LEVINE (p 59) shows that the changes are quite similar to those found in epidemic typhus—haemorrhages, perivascular exudation, consolidation of the lower lobes of the lungs. Oedema of the ankles, or collection of fluid in serous cavities, is common. It seems likely that patients who recover show no residual cardiac damage.

TULLIS *et al* (p 895), as a result of examining mice, monkeys and one man infected with the Karp strain of *R. orientalis*, are inclined to think that in

scrub typhus, damage to the endothelium of the vessels is much less severe than in Rocky Mountain fever and epidemic typhus but MacGaw demurs at this, pointing out that different strains of infecting organisms produce lesions of different severity and quoting other authors who have not found essential pathological differences between the diseases.

WELL and HAYMAKER (p. 577) report on the pathology of the nervous system in scrub typhus. The chief changes found in 21 fatal cases were engorgement of the vessels of the leptomeninges and cerebrum sometimes with marked cellular infiltration. Focal nodules were few.

Tests.—In a series of patients with scrub typhus, from Burma and the Philippines, whose sera were examined at various stages by the complement fixation reaction in which three strains of rickettsiae were used, BANGROUX (p. 60) found remarkable variations in response. There is, however, no clear differentiation of serological types. Higher and more persistent titres were obtained with this than with the Weil-Felix test. The same author (p. 61) describes the preparation of an antigen from a strain of scrub typhus rickettsiae from Malaya. The organism was grown in yolk sac culture and the antigen was specific for scrub typhus giving negative results with other diseases, including those of the typhus group. She (p. 304) describes how the complement fixing antigen is separated from suspensions of scrub typhus rickettsiae.

BELL *et al.* (p. 514) have noted antigenic differences in three strains of *R. orientalis* as measured by cross-neutralizing tests.

Clinical and general treatment.—SAYEN *et al.* (p. 305) report on 200 cases of scrub typhus in American soldiers in Assam and Burma. It was not possible in the first week of illness to tell if the attack would be mild or severe. There was a primary lesion in 60 per cent and this with lymphadenopathy, rash, engorgement of retinal veins or oedema of the retina and Weil-Felix (OXA) 1 in 100 or more was a useful diagnostic sign. Some degree of pulmonary involvement was usually present as was albuminuria. The nervous system was involved in a minority of cases, and haemorrhages were common in several cases. Convulsions, hyperpyrexia, restlessness, tachycardia and cyanosis were ominous signs; the case mortality rate was 8.5 per cent though in other series it was lower than this.

RIPLEY (p. 200) notes that in one outbreak of scrub typhus in the Pacific all patients showed some involvement of the central nervous system from transient toxic cerebral symptoms to evidence of widespread inflammation with coma and death. The pathological lesions found were similar to those seen elsewhere in the body, focal lesions with necrosis, thrombosis and perivascular infiltration. Many of the patients showed residual manifestations which seemed to be secondary to the changes in the nervous system but psychotherapy was of some value.

TEXTORSON (p. 826) describes 58 cases of scrub typhus and 4 of urban typhus in troops near Kuala Lumpur. The latter could be differentiated from scrub typhus without delay only by the results of the Weil-Felix test and by its relatively mildness.

McLIMANS and GRANT (p. 46) show that methylene blue given with food in a concentration of 0.2 per cent is trialingly effective in reducing fatality from scrub typhus in Swiss mice especially when combined with administration of oxygen even when started as late as 147 hours after inoculation. Para-aminobenzoic acid was less effective. PETERSON and FOX (p. 613) report that if methylene blue or toluidine blue is given in food to mice infected with the hard strain of *I. ricinus* even as late as 300 hours after the onset there is a substantial therapeutic effect. The corresponding dose could not be tolerated by human beings and intravenous injection in adequate dose causes

haemolytic anaemia Nevertheless, the results are encouraging, especially when *p*-aminobenzoic acid is given at the same time

Vaccination—LEWTHWAITE *et al* (p 410) describe the techniques they adopted in cultivating *R tsutsugamushi* (*R orientalis*) in the yolk sacs of hens' eggs, for the purpose of preparing vaccines Details should be sought in the original Antigens suitable for complement-fixation and rickettsia-agglutination tests could not be obtained in this way [It will be remembered that vaccine for scrub typhus was eventually obtained from infected lungs of cotton rats] HENDERSON-BEGG and FULTON (p 577) standardized the scrub typhus vaccine prepared from lungs of cotton rats by a simple technique for counting the rickettsiae WALKER (W T) (p 706) shows that scrub-typhus vaccine prepared in England was effective in reducing the severity of attacks of the disease, in 16 cases, even if only one dose had been given On the other hand, CARD and WALKER (J M) (p 707) could find no satisfactory evidence that the attacks were favourably influenced in 33 men in S-E Asia Not all had received the full course

Indeterminate type vector tick

STEINITZ (p 307) reports, for the first time, a case of boutonneuse fever in Palestine

BENGTON (p 812) discusses nomenclature of the rickettsiae of Rocky Mountain fever and of murine typhus, readers should consult the original for details

HUMPHREYS and CAMPBELL (p 758) have found evidence of infection with Rocky Mountain spotted fever in collections of *Dermacentor andersoni* made in British Columbia and Alberta They make the point that failure to recover *R rickettsi* from ticks should not be relied upon as an indication that an area is free from infection, there may be strains which are mild for guinea-pigs but virulent for man BUSTAMANTE and VARELA (p 656) found *Amblyomma cayanense* naturally infected with Rocky Mountain spotted fever in Veracruz, Mexico

VALLEJO-FREIRE (p 708) shows that the rickettsia of tick-borne typhus of Mexico is apparently identical with that of Rocky Mountain spotted fever of North America and of Brazil He proposes the name spotted fever for this disease, but in comment MEGAW shows that this name, which has been applied to other diseases, is less suitable than tick-typhus

Discussing the Weil-Felix reaction in Rocky Mountain spotted fever, PLOTZ (p 201) stated that the usual reaction is of the *Proteus OX19* type, but that the *OX2* titre is sometimes high, and that if it is 1 in 320 or more the disease can be suspected. In comment MEGAW draws somewhat different conclusions from the data given, and thinks that either the *OX19* or the *OX2* titre may vary from 0 to + + + +

DE PAULA (p 201) describes vesicles on the palate and white ulcers on the fauces, in cases of typhus [presumably tick-borne] in Minas Gerais

FLINN *et al* (p 413) report good results from *p*-aminobenzoic acid in human cases of Rocky Mountain spotted fever It is rapidly excreted in the urine and repeated administration is therefore necessary The authors gave 4-6 tablets (each of 0.5 gm) every 2 hours, to a total dosage of 50.4-327 gm RAVENEL (p 708) writes very favourably on the effect of *p*-aminobenzoic acid in Rocky Mountain spotted fever, as a result of its use in 5 cases ANIGSTEIN and WHITNEY (p 412) think that administration of calcium gluconate together with *p*-aminobenzoic acid increases the value of the latter in experimental Rocky Mountain spotted fever in guinea-pigs

Complement-fixation reactions were carried out on the sera of 40 patients (in India) whose Weil-Felix reactions were of the *OX19* or *OX2* type, by

SEATON and STOKER (p. 578) who used murine and Rocky Mountain spotted fever antigens. Of 18 positive for murine typhus the Weil-Felix was of OX19 type in 14 of 16 positive for Rocky Mountain fever 12 gave the OX type of reaction. Controls were negative. The authors therefore regard this as further evidence of the presence of tick typhus in India. KASRA (p. 575) has isolated strains of rickettsiae (one from a patient in Poona and one from *Haemaphysalis leachi* var. *indica* in Imphal) which show some antigenic relationship to *R. rickettsii*.

PRONIKHINSKI (p. 886) describes the tick typhus of the Soviet Far East which is probably transmitted by *Dermacentor jiturnum* and *Haemaphysalis concinna*. PETRIJARI (p. 515) in Soviet Asia describes a disease which he claims is tick borne and in which after a febrile period of 8-10 days, the Weil-Felix reaction with *Proxenus* OX19 becomes strongly positive.

A small outbreak of tick typhus was reported by ANDREW *et al.* (p. 222) from Queensland, Australia. There was an eschar with associated lymphadenitis in most of the cases and in two an adult tick was found at the site of the lesion. It seems likely that *Ixodes holocyclus* is the tick concerned, but others occur in the area. The Weil-Felix reaction gave results somewhat like those reported in Rocky Mountain fever but complement fixation tests on the sera of the patients failed to show any immunological relationship with that fever or with S. African tick bite fever boutonneuse fever epidemic or murine typhus. The rickettsiae were cultivated by PLOTZ *et al.* (p. 204) and the sera of animals infected with them reacted to the homologous antigen but not to the antigens of other fevers of the typhus group including Q fever though there was some rather indefinite evidence of immunity to S. African tick bite fever and murine typhus which may have been non-specific. The rickettsia is probably a hitherto undescribed species. FURBER and JACKSON (p. 204) report their laboratory comparison of these tick typhus rickettsiae with murine strains: there was some incomplete cross immunity. FURBER (p. 514) found low titre positive complement fixation reactions with the sera of opossums, bandicoots etc. tested with an antigen from a rickettsia of North Queensland tick typhus. The animal were from an area in which the disease had been reported.

Q fever

In 1945 a disease which occurred in British and American troops in Italy and which had previously been found in Greece was shown to be Q fever. The diagnosis made before this identification was atypical pneumonia and Balkan grippé. Q fever had not hitherto been seen outside Australia and the United States. A series of papers in the *American Journal of Hygiene* describes the steps of its identification made—

KOBIK and RAGAN (p. 67) show that the onset was sudden with fever and cough. Signs of patchy consolidation of the lungs appeared, verified by X-ray. There were no deaths. Blood cultures were sterile the Weil-Felix test negative but *Rickettsia burnetii* was isolated 16 times in 21 attempts by inoculation of guinea-pigs, sulphonaemides and penicillin needles.

In five of the outbreaks the possible modes of infection were studied and KOBIK, GUILD and WALKER (p. 63) noted that the men affected in one unit were those who had slept in or entered the loft of a barn in which pygmies, rats, larval ticks, fleas and mites were found. They think that as few of the men complained of bites an insect vector was unlikely but inhalation of dust containing dried secretions of animals may have been a factor. The so-called person-to-person transmission.

The rickettsiae were isolated from 16 patients through guinea-pigs, they grew readily in yolk sacs of chick embryos. KOBAYASHI, RICHARDS and WALKER (p. 64) show that different strains from Italy and America, gave

different results with the complement-fixation test on sera from human cases and from guinea pigs, these differences are probably quantitative, and they were not apparent in the rickettsia-agglutination test

ROBBINS and RUSTIGIAN (p 65) think that in the laboratory outbreak which occurred in Italy, the infection was probably acquired by inhalation of air infected usually in the process of yolk-sac culture work

FEINSTEIN *et al* (p 66) describe the symptoms and signs of 143 men whose attack of Q fever began in the United States after a voyage of 9 days from Naples. In most of them there were middle- and lower-zone pulmonary lesions visible on X-ray, which differed in distribution and character from those of primary atypical pneumonia. Similar signs were seen in some men who had no symptoms. Diagnosis was confirmed serologically.

The U.S. Commission on Acute Respiratory Diseases (p 67) could find no explanation of this outbreak, which involved other units which had been at the same camp in Italy. They think that an arthropod vector may have been involved, while the men were cleaning the camp before leaving it, and were sleeping in the open. The causal organism was not isolated, but complement-fixation tests were usually positive in rising titre. Some positive results were found in another unit which had apparently escaped infection. The Commission (p 68) gives details of the identification and characteristics of a strain of Balkan grippé rickettsiae isolated in guinea pigs in Greece. Sera of guinea pigs inoculated with this strain, and of human patients, gave positive complement-fixation tests with antigens from Australian or Italian *R. burneti*, and rickettsia-agglutination tests on sera of guinea pigs or patients gave similar results with this and the Australian and Italian antigens.

The Commission (p 69) recounts the history of the laboratory infection referred to above; rickettsiae were isolated from the blood of some patients and the pleural fluid of one. Symptoms were severe, but the infecting dose (presumably inhaled during manipulation of infected yolk sac material) may have been heavy.

CHENEY and GEIB (p 70), having seen cases of atypical pneumonia in Panama, inoculated guinea pigs with the blood of some of the patients, and found that one of them was a case of Q fever, of which the rickettsiae showed cross immunity with the standard American strain. The patient had been in the area for 3 months; no indication of the mode of transmission was found.

TOPPING *et al* (p 70) show that 6 strains of Q fever rickettsiae from widely different sources grew readily in yolk sac cultures and were similar in morphology. Five of them showed complete cross immunity (the sixth could not be tested) but the various antigens were not equally sensitive in the complement-fixation test.

BLANC *et al* (p 709) isolated three strains of *R. burneti* from *Hyalomma savignyi* (? *H. aegyptium*) in southern Morocco. BLANC *et al* (p 898) give reasons for their view that the gerbil *Meriones shawi* is a host of Q fever in Morocco, where *Hyalomma savignyi* is the vector.

HUEBNER (p 709) describes an outbreak of Q fever at the National Institute of Health, Bethesda, U.S.A., where 6 strains were being investigated. The outbreak was closely associated with preparation of yolk-sac antigen, involving high-speed centrifugation and treatment with 0.5 per cent formalin, which has not been found lethal to this rickettsia. In comment, Megaw remarks that it is difficult to reconcile the findings with any other hypothesis than the inhalation of droplets of infected yolk-sac material. Persons who had suffered from the disease during an outbreak in 1940 were not this time affected, and persons who had received Rocky Mountain fever vaccine were apparently protected to some extent, but not completely; typhus vaccination did not confer any protection. The incubation period was 13-18 days.

TOPPING and his colleagues (p. 710) describe an outbreak of Q fever in stock handlers and slaughterhouse workers in Texas who were probably infected by dust derived from material contaminated by the excreta of a group of apparently healthy cattle. There was no evidence of transmission by ticks. Autopsies usually revealed lesions similar to those of atypical pneumonia. In complement fixation tests with Q fever antigens, rising titres were found to 1 in 320 in 4-5 weeks. *R. burnetii* was isolated from two patients through mice, and yolk sac cultures were readily obtained.

Rickettsialpox and other diseases

The newly recognized rickettsialpox is described by HUBBARD *et al.* (p. 411) from New York, where an outbreak of 80 cases took place. The clinical features resemble those of chickenpox, but rickettsiae were isolated through mice from one of 15 patients. There is apparently some degree of cross immunity between this disease and Rocky Mountain spotted fever.

GREENBERG *et al.* (p. 707) describe rickettsialpox. Almost all patients showed a primary lesion—a papule which became a vesicle and then a scar. The onset of fever was sudden and the fever was remittent, ending by lysis in 1-10 days. A rash was present in all cases, lasting 4-7 days, and becoming macular. Positive complement fixation tests were given with an antigen prepared from rickettsiae from one patient but this antigen did not react with sera from patients with certain other rickettsial diseases, though it did with sera from Rocky Mountain spotted fever.

GREENBERG *et al.* (p. 690) give details of the epidemiology of rickettsialpox. Mites (*Holothymannys sanguineus*) were found on the walls, furniture, floors and on mice and the authors point out that if incinerators are irregularly used they conduce to mouse infestation. HUBBARD, JELLINEK and LOMSKY *et al.* (p. 411) isolated two strains of the rickettsia of this disease (*R. akari*) from mice (*Holothymannys sanguineus*) collected from mice and from the walls of incinerators in the areas concerned. Other strains were also isolated from pools of mites, but could not be cultivated in fertile eggs. One of the floors was attacked by the disease three weeks after collecting the mites. HUBBARD *et al.* (p. 697) have recovered *R. akari* from naturally infected mice at the end of the outbreak of rickettsialpox and have identified them by various tests. The mice appear to be the natural reservoirs of the disease.

In an interesting paper BURTON (p. 206) describes a hitherto unrecorded species of rickettsia which gives an inapparent infection in voles and is found in the St. Lawrence River, Canada. This is immunologically closely akin to the harp strain of *A. orientalis* and is probably transmitted by mites (*Trombidium* sp.) found on the voles and from which rickettsiae were recovered.

A laboratory outbreak of trench fever in persons employed in feeding large numbers of lice for the preparation of World War vaccine is described by CODELLONCHI (p. 307) from Aden, Arabia. He thought it be clear were found to be harbouring rickettsiae which were apparently identical with *R. quintana*. The symptoms were typical of trench fever. BURTON (p. 1081) and SCHULZ and KATZ (p. 1161) give their reasons for thinking that one form of field nephritis seen during the war may have been due to *Rickettsia* sp. *novae*.

NEIJMANN (p. 46) claims to have cultivated rickettsiae in the absence of living cells. With DOUGLASS (p. 57) he describes rickettsial leucocytes in the Congo. He states that the finding of rickettsiae in the urinary sediment is one of the best methods of diagnosis. He (p. 57) shows that the mouse protection test for yellow fever remains valid for patients with Congo fever. He has noticed (p. 5) that healthy laborers can quite easily harbour rickettsiae.

indistinguishable from those which he has cultivated from the blood of typhus patients, but this latent rickettsial infection does not interfere with the use of the animals for typhus work

BARLOVATZ (p 810) describes an attack of a typhus-like fever, with Weil-Felix reaction (*Proteus OX19*) positive to 1 in 640, which he himself had some 3 months after leaving the Belgian Congo. He suspects that it was the Congo form of typhus with prolonged incubation period. *Charles Wilcocks*

RABIES

VEERARAGHAVAN, N. Further Observations on the Cultivation of Rabies Virus *in vitro* *Indian J Med Res* 1947, Oct, v 35, No 4, 237-53 [12 refs]

The author has previously claimed [see this *Bulletin*, 1947, v 44, 635] that the aetiological agent of rabies can be cultivated *in vitro* in a medium consisting of sheep brain extract with various additions, and that for this reason it may not be a true virus. In a continuation of this work it is stated that the addition of tryptophane, thiamin, pyridoxine and pantothenate increased the amount of virus obtained in cultures. The maximum titres observed were 5×10^9 LD₅₀ per cc, which were obtained 24 hours after adding virus to the culture medium at a concentration of 5×10^5 LD₅₀ per cc. Propagation of virus in culture was observed through 4 passages.

[This latter fact, together with the high titres reported in this paper, certainly supports the author's claim that true multiplication is occurring, as opposed to an apparent rise of titre caused by dispersion of virus aggregates or the breakdown of combinations with inhibitory substances. Independent confirmation will be awaited with interest.] *D J Bauer*

MALARIA

J. NATIONAL MALARIA SOC 1948 June v 7 No 2 148-56 *Medical Research in Malaria* 1947 Report of the Committee on Medical Research [HAAS V H, Chairman]

NOYAN, A. Summary of the Free Lecture on Malaria *Acta Med Turcica* Ankara 1948, v 1, No 1, 32-7, 2 folding maps

This summary of a lecture which was given at the Ankara Numune Hastanesi in May 1946 is semi-popular, but gives some useful information on the distribution and control of malaria in Turkey.

The malarial regions of the country are shown in a shaded map, prepared by the author for the first Turkish Medical Congress in 1925. This indicates the "first malarial region" which includes districts having average parasite and spleen indices of 25 per cent or more, and comprises the coastal regions, great river beds and the south-eastern part of the country. The "second malarial region" includes the mountains and high plateaux where the disease is usually introduced from the first malarial region, but where it is not ordinarily prevalent. An anti-malaria campaign has been in action since 1924, and although it was somewhat relaxed during the war, it has been intensified in the last two years with good results. In the army, for example, where statistics are readily available, cases of malaria have fallen by half.

The common anophelines are *A. maculipennis*, *A. sacharti*, *A. superpictus*. In South Turkey and near Palestine *A. levrieri* and *A. sergenti* are encountered.

Epidemiological conditions are favourable to malaria along the Black Sea and Mediterranean coasts, the river beds, in South-East Turkey and in those parts of Anatolia below 1,000 metres.

In the warmer valleys along the Mediterranean coast malaria may begin in April-May and last until October-November. Benign tertian malaria is relatively common but in some districts the subtertian form is more frequent. Quartan malaria is less common. Cases reported to the first Medical Congress from various hospitals amounted to 9,971 and comprised 5,438 benign tertian, 4,140 subtertian and only 395 quartan infections.

Malignant forms of the disease are not met with as commonly as they are in the tropics and they are not usually fatal. In the first world war the Turkish Army recorded 400,000 cases of malaria with a mortality of 4.8 per cent. In 1944-45 the death rate was as low as 0.4 to 0.33 per cent.

Control presents difficult problems: the malarious districts are the richest and most fertile and attract thousands of workers yearly from the less fertile Anatolia: the crop time coincides with the malaria season and the workers sleep out of doors, often on flat roofs or in gardens. Some of the houses have thatched roofs which harbour mosquitoes and pools are maintained in some villages to provide water for buffaloes and ducks.

Drug prophylaxis with various formulations of quinine and of atabrine (mepacrine) has been employed and the various methods compared but comparable results were not available at the time when the paper was published.

SAUTET J, RANQUE J, VAILLET F & VAILLET J. Quelques notes parasitologiques sur le paludisme et l'anophélie en Mauritanie. [Some Parasitological Notes on Malaria and Anophelines in Mauritania.] *Méd. Trop. Marseille*. 1948, Jan. Feb., v 8, No. 1: 32-9 (1 map).

In a rapid and incomplete survey of parts of Mauritania (French W. Africa) the following anophelines were found: *Anopheles gambiae*, *A. fuscus*, *A. pharoensis* and *A. rufipes*. The dates of capture in some half-dozen localities are given. Adults were taken in houses and their buildings and larvae in both temporary and permanent waters. Of 307 blood slides examined 180 were positive as follows: *Plasmodium falciparum* 133 (52 from children under 15 years of age), *P. malariae* 33 (8 children under 15), *P. vivax* 14 (5 children under 15). Of gametocyte carriers, 4 had *P. malariae* and 22 *P. falciparum* and *P. vivax*. The authors draw attention to the predominance of *P. falciparum* infections, the rarity of *P. malariae* and the still greater rarity of *P. vivax* but they admit that owing to the small numbers examined they are unable to draw any conclusions.

H. S. Lewis

MCDONELL, G. E. & HENDRICKS, F. M. *Plasmodium malariae* in School Surveys in South Carolina. *J. National Malaria Soc.* 1948, Mar., v 7, No. 1: 65-75 (2 maps, (11 refs.))

Between 1937 and 1943 the South Carolina State Board of Health carried out thick film blood smear surveys among school children in 23 counties. Altogether 108,553 smears were collected from 560 schools for white children and from 918 schools for coloured children. Of this total 10,245 were from 13 schools for white children and 77 schools for coloured children in which the 295 positive *P. malariae* blood films were found. The percentage positive

P. malariae films for white children were 0.64 and for coloured children 3.23 thus *P. malariae* infection is primarily an infection of the coloured race in this State

One or more schools in 15 counties gave positive *P. malariae* smears, in only 8 of these counties were white children found infected. The counties with most *P. malariae* infection were Calhoun, Berkeley, Dorchester, Orangeburg, Sumter, Georgetown and Clarendon. Infection is concentrated along the course of the upper Santee River. *P. malariae* was found most frequently in smears taken in December. Norman White

VUILLET, J. & LEVAVASSEUR, G. Excitation biologique des ultra-sons sur des oeufs d'*Anopheles maculipennis* [Biological Stimulation of *Anopheles maculipennis* Eggs by Supersonic Rays] *Méd Trop* Marseille 1947, July-Oct, v 7, No 4, 343-6, 3 charts

Eggs of *Anopheles maculipennis* were exposed to supersonic radiation produced by powers ranging from 250 milliamperes to 1,200 milliamperes. The periods of exposure varied from 15 seconds to 15 minutes. In some experiments the radiations were concentrated by a concave mirror and in others reflected from a convex surface. The rate of development of the larvae hatching from these eggs was studied and compared with that of larvae from normal untreated eggs. It was found that the rate of development was accelerated in those larvae from eggs which had received radiations at powers above 1,050 milliamperes concentrated by the concave mirror. For instance, larvae were still in the first instar and only reached the third stage after nineteen days. In a few trials done with a convex mirror, no acceleration of larval development was observed. Other trials indicated that, varying the period of exposure, within the experimental limits, at any one power made little difference, and in July when the mean temperature of the water was 26°C, larvae from treated eggs were still more advanced than those from normal eggs, just as in May when the average water temperature was only 20°C.

In discussing this phenomenon, the authors discard the effect of heat as a cause because with an exposure of 15 seconds they say the water had no time to warm up, but the reviewer cannot help feeling that there may be a local transitory thermal stimulus which they have overlooked. It appears that only a few eggs can withstand the radiations and remain floating, these hatch but the majority burst and sink, thus showing that such treatment is very near the threshold of destruction. COUTINHO, J. de O. Contribuição para o conhecimento das espécies do subgênero *Kerteszia* (Diptera Culicidae). Sua importância na transmissão da malária. [Observations on the Sub-genus *Kerteszia* and its Importance in the Transmission of Malaria] [Thesis for Doctor's Degree] Universidade de São Paulo, Faculdade de Medicina 1946. 87 pp. 2 maps, 2 text figs and 12 figs on 3 pls [Bibliography] English summary

DULANEY, Anna D. with the technical assistance of Jane B. Priest, Mary L. Almeida & B. Parker. The Complement Content of Human Sera with especial reference to Malaria. *J Clin Investigation* 1948, May, v 27 No 3, Pt 1, 320-26, 6 figs [18 refs]

With the use of a modification of the method of Kent, Bukantz & Rein [see *Journal of Hygiene*, 1946, v 21, 775] the amount of complement in the blood

of (1) 30 normal individuals, (2) 23 persons with liver disease, (3) 32 persons with non-infectious diseases and (4) 74 neurosyphilitics before and after induced malaria (presumably P. falciparum though this is not stated) was determined.

The authors reach the following conclusions —

1. The over-all complement content of normal human sera (as based on the amount in milliliters required for 50 per cent. hemolysis) is remarkably constant.

2. The 50 per cent hemolytic unit for normal individuals, as determined by the method employed by us, ranged from 0.0032 to 0.006 ml. with a median of 0.0045 ml.

3. Day-to-day variations in the complement content of normal individuals appear to be slight.

4. The complement level of sera (one sample) from patients with liver disease and from patients with non-infectious diseases of various types did not appear to be depressed. There was no correlation between complement titer and the results of the cephalin-cholesterol test.

5. Complement is usually diminished during the course of induced malaria. This decrease may be very slight or in severe disease it may be very marked. In general the complement titer reflects the severity of the disease, the balance between host and parasite. Complement titer cannot be correlated with parasite count, white blood cell count, temperature, number of paroxysms, hours of fever, cephalin flocculation test or antibody titer.

6. In any study of complement as related to a particular disease it is important that a series of determination be carried out at short intervals during the course of the disease in order to detect changes which may occur.

DIAMOND, C. Malaria before report. [Diagnosis of differential clinical. Clinical Differential Diagnosis of Malaria and Relapsing Fever] Bull. Soc. Ind. et Med. Igou 7 of (Sex. Int.) 1947 7 Nov 5 p 416—English summary (2 lines)

DAWLEY, C. PROST & CARR, K. L. case d'acut peracute paludisme. A Malignant Attack of Malaria in an Infant of Three Months. Bull. et Mem. Soc. Med. Hôp. de Paris 1947 Nov 7 p 114—117 fig.

RAJ, L. Malarial Diabetes. Report of a Case. Lancet 1948 July 3 111 fig.

A man of 43 returned from India in June 1947 after six years residence there. A few weeks later he suffered from frequency, thirst, anorexia, weight loss and loss of weight. He had had malaria at the age of 19. There was no significant family history.

On examination on August 21st, glycosuria was present but no acetone bodies were found. Ring forms of *Plasmodium falciparum* were found in the blood.

Next day the patient's fasting blood sugar was 350 mgm/100 cc. Two days later he became worse, he felt drowsy and could not walk unaided. The fasting blood sugar was unchanged but the glycosuria was heavy and acetone bodies were present in the urine. He was given 30 units of insulin three daily and a diet of 2,500 calories. Next day his fasting blood sugar had dropped to 182 mgm/100 cc. For two weeks the patient improved the glycosuria disappeared, but the fasting blood sugar was still elevated. On September 17th,

when insulin had been reduced to 30 units twice daily, leading to the reappearance of glycosuria, Paludrine was given in a dosage of 0.1 gm twice daily for 10 days. The urine then became sugar-free, although the diet was unchanged and the insulin dosage was 30 units a day. By October 9th, the fasting blood-sugar was 104 mgm/100 cc and by the 31st, the patient was no longer on a restricted diet nor was he receiving insulin.

Three months later, after consistently negative weekly examination of the urine for sugar, the result of a sugar tolerance test was within normal limits.

The author considers that the diabetes was caused by malaria affecting the islets of Langerhans. He refers to two cases of severe subtertian malaria, with sudden death, sections from which were shown to him by Professor R. J. V. Pulvertaft, in these, the capillaries of the islets of Langerhans were completely blocked by red blood corpuscles loaded with parasites (one of these sections is illustrated in the text).

It is presumed that a similar pathological process occurred in the present case, in which the diabetes could be controlled by diet and insulin, and was cured by Paludrine.

H. J. O'D. Burke-Gaffney

EYLES, D. E. & YOUNG, M. D. Studies on Imported Malarias. 7. The Parasitological Pattern of Relapsing *Plasmodium vivax* in Military Patients. *J. National Malaria Soc.* 1948, Mar., v. 7, No. 1, 23-37, 3 figs.

In their studies of relapsing *P. vivax* malaria acquired overseas, the authors examined the blood of their patients twice a week after the treatment of clinical attacks. In 77.2 per cent of relapse attacks in 351 patients under observation, parasites were found in the blood before fever occurred, this percentage would have been higher had daily blood examinations been practicable. On the average the first parasites were found 3.5 days before the febrile paroxysm. The median fever threshold parasite count for over 800 relapse attacks was 3,200 per cmm (mean 6,300). For Pacific cases these figures were 2,952 and 6,030, for Mediterranean cases 3,836 and 7,250. No significant variation in parasite level was found between early, middle and late relapses.

Pacific cases showed male gametocytes to be present in 29.4 per cent of 659 attacks against 55.7 per cent in the case of 185 Mediterranean attacks, a highly significant difference. Patients with or without gametocytes during one relapse were likely to be with or without, respectively, during the subsequent attack.

Delayed primary attacks, nearly all from the Pacific, occurred on the average 49.1 days after suppressive atabrin had been discontinued. Extreme intervals were 7 and 167 days. The median value of the first parasite count after onset of fever in delayed primary attacks was 870 per cmm for 197 cases. In 63 of these cases in which the onset of symptoms was reported promptly, the median value was 150 parasites per cmm.

The mean interval, without regard to the drug used, from the onset of one to the onset of the subsequent clinical attack was 61.1 days, most relapses had taken place by 120 days. Most patients had no demonstrable parasite activity between relapses but about 12 per cent had transient low-level asymptomatic parasitaemia 56 days (average) after the onset of the previous clinical attack and lasting 12 days (average), varying from one to 62 days.

Three hundred and fourteen patients were kept under observation for four months or longer after their last clinical attack. About 25 per cent of these showed terminal asymptomatic parasitaemia, about half of these persisted for more than a month. These parasitaemias were both remittent and intermittent. They were first observed about 80 days (average) after the last

observed clinical attack. Levels attained by these parasitaemias were usually only one fourth to one half the levels noted in the same patients at the time of the previous clinical attack.

Malaria parasites were present in the peripheral blood of Pacific malaria patients 13 per cent. of the time and in Mediterranean patients about 10 per cent. of the time. In both groups, 75 to 80 per cent. of the time of parasitaemia was asymptomatic.

Norman H. Hine

SPITLER D. K. Malaria Relapse. Report of a Case Thirty-Six Years after Original Infection. *New England J of Med* 1948, June 10 v 238 No. 4 839.

The author describes the case of a Sicilian labourer of 69 years who had lived in the vicinity of Cleveland, Ohio for the previous 36 years. Previously he had been many years at sea and had called at ports as far as the South Pacific. He stated that he had had one attack of malaria in Sicily, but could not recall his age at the time. He denied any recent hypodermic injections.

He was admitted to hospital complaining of fever "at 4-day intervals" and on that day and the next many *Plasmodium malariae* parasites were found in his blood. He was treated with quinine and made an uneventful recovery without further febrile illnesses. The author points out that in this case reinfection was highly improbable and that the case appears to have been a genuine relapse. The importance of keeping a diagnosis of malaria in mind in these cases is emphasized. Latency of this nature indicates the inadvisability of using as blood donors persons who have ever had malaria in the past.

It is suggested that the determining cause of the relapse in the present case may have been trauma, as the patient had fallen on the curb a few days before the onset of his chills, and struck the left side of the trunk, i.e. over the area of the spleen where he had a painful lump on admission.

H. J. O. D. Burke-C. (Jury)

MAKER, J. HANG F. B. & HAINSTON, G. A Comparison of the Effectiveness of Quinacrine and Quinine against *Falciparum* Malaria. *Trans J T P Med.* 1948, May v 28 No. 3 401-6.

This work was carried out during the war in the 27 Australian General Hospital. Ninety nine patients with *P. falciparum* malaria were treated with quinacrine (mepacrine) and 104 with quinine. The course of treatment lasted 6 days in both groups. The daily doses were divided into 3 parts and were —

Quinacrine 1 2, 0.8, 0.4 0.4 0.4 0.4 grammes.

Quinine hydrochloride 40 40 40 30 30 30 grains.

Patients in both series responded rapidly to treatment. There was no appreciable difference between the two series as regards the rate of disappearance of fever or the rate of disappearance of parasites from the peripheral blood. There was no significant difference in gametocyte production in the two series.

Of the 99 patients treated with quinacrine 6 developed nervous symptoms 4 transient maniacal states and 2 epileptiform convulsions.

It was found that adequate plasma levels could be obtained when the total quinacrine administered was reduced from 3.0 to 3.6 gm.

PARAMJOOTHY J. T. Notes on some Cases of Atabrin Psychosis. *Med. J Malaya.* 1947 Sept. v 2, No. 1 49-51

The author describes four cases of atabrin (mepacrine) psychosis in Malaya. The first was that of an Indian Mohammedan who suffered from malaria in 1944.

The author concludes as follows —

“—— A dosage of 300 mg given as a single dose was successful in resolving the clinical attack in 3 days in 81 to 87 per cent of cases in all types of infection both as regards fever and parasites ”

Parasitic relapses occurred after this treatment in all three infections

iii This trial was conducted at the Carmichael Medical College, Calcutta, on 20 patients suffering from clinical malaria with parasitaemia (10 *falciparum*, 6 *vivax*, and 4 mixed infections) These had had no antimalarial treatment for at least 6 weeks prior to treatment with paludrine The dosage employed in 6 cases (4 *falciparum*, and 2 *vivax*) was a single one of 100 mgm, and in the others 100 to 200 mgm daily for 2 to 5 days

The author gives the following summary —

“—— paludrine is a safe drug to use and will stop clinical attacks of malaria in doses which produce no untoward symptoms In the above series a minimum single dose of 100 mg, and a maximum of 700 mg, in five days were required to make the patient fever free and parasite free It had little effect on the sexual forms of the parasite —— ”

iv This study was made at the Medical College Hospital, Calcutta, on 58 cases of malaria (20 *falciparum* and 38 *vivax*), with parasitaemia These were treated in 5 groups with doses of paludrine ranging from 600 mgm daily for 2 days followed by 300 mgm daily for 5-6 days [total 3,000 mgm] down to 200 mgm daily for 2 days only All were free of parasites by the 96th hour of treatment, but the pyrexia persisted in some cases beyond this, and was usually evident for a day or two after the blood had become negative

The author considers the drug “an excellent and effective remedy”, and thinks dosage must be continued after the peripheral blood is clear of parasites as the fever persists after this

v This work was done in the Sir J J Hospital, Bombay, on 50 cases of malaria with parasitaemia (26 *vivax*, 20 *falciparum*, 3 *malariae*, and 1 mixed) The dosage employed ranged from a single dose of 100 mgm to 600 mgm daily for 10 days [total 6,000 mgm] The variation in dosages had little influence on the immediate result, all attacks ending in a few days Subsequent dosage once weekly, it is suggested, “could indefinitely prevent malarial infection from recurring ”

vi This study was undertaken in two isolated areas under the control of the Assam Railway and Trading Co, Ltd The experiment was to determine (1) a satisfactory suppressive dosage of paludrine in those not suffering from acute malaria and (2) the dosage necessary to control an acute attack of the disease In the first trial, a dose of 100 mgm of paludrine once a week was given as a prophylactic to 1,678 persons, 294 others untreated served as controls This dosage for various reasons was not found adequate, so 100 mgm of paludrine was then given twice weekly to 1,075 and 200 mgm once weekly to 800 persons, 246 remained untreated as controls Two hundred and thirty-five acute attacks of malaria (152 *falciparum*, 61 *vivax*, 15 *falciparum* + *vivax*, and 7 *malariae*) were treated with single doses of 100 mgm or of 300 mgm of paludrine, or with 200 mgm daily for two days

The author reaches the following conclusions —

1 As a suppressive, one tablet (100 mg) of paludrine once a week would probably be adequate, but when dealing with mass administration to a disinterested population a certain number are bound to miss the weekly dose for one reason or another One tablet (100 mg) twice a week reduces the chances of any one going a full fortnight without the tablet

2 The success of suppressive measures is directly proportional to the efficiency of the administrative controls

two days of treatment and did not reappear during the period of observation in the remaining 17 cases typical febrile attacks occurred at some time after the first five days of treatment. Asexual parasites disappeared from the peripheral blood after the first or second day of treatment. Gametocytes appeared in the blood of 51 of the 94 patients infected with *P. falciparum* after the 5th day of treatment.

P. malar parasites disappeared from the blood within 2 or 3 days of the beginning of treatment except in one case in which they persisted for 4 days.

In the *P. malariae* patient parasites persisted in the blood for 6 days.

- vii. AFREIDI M. K. A Critical Review of Therapeutic Trials on Paludrine carried out in India during 1946. *Ibid* 347-60.

i. This trial was conducted in village community. The dosage of paludrine employed was a single one of 300 mgm. administered by the medical officer personally. Alternate cases were treated with 300 mgm. of mepactine daily for 3 days. During the period 11th September to 31st December 1946, 129 cases were treated: 8 with paludrine and 62 with mepactine. Of the 8 paludrine-treated cases 37 were due to *P. falciparum* and 22 to *P. malar* while 17 showed no malaria parasites. Of the mepactine treated cases 29 were *falciparum*, 20 *malar* and 1 *malariae*. 17 were blood negative.

From this observation the author concludes:—

"(I) Paludrine in the dosage in which it was administered (300 mg. single dose) controlled malarial attack quicker than mepactine. The fever touched normal in 74 hours in 4 per cent of paludrine treated cases against 16 per cent of mepactine-treated cases.

"(II) In an hyperendemic area like that of the Naini Tal Tarai it is very difficult to evaluate the relapse preventing properties of paludrine because of the difficulty to ascertain whether a person had actually relapsed or had been reinfected. If the case which had a recurrence of fever in those areas were cases of relapse paludrine did not show any advantage over mepactine in relapse-preventing properties.

(III) No toxic effect were noticed.

ii. This trial was conducted in hyperendemic malarial area in a rural setting 35 miles from Calcutta. A single dose of 300 mgm. of paludrine was given to adult patients a half or third of this to children under 1 year of age. All doses were given personally by the medical officer. Of the 49 patients treated only 16 had a parasitaemia (119 *falciparum*, 0 *malariae*, 17 *falciparum*, 11 *falciparum malariae* and 15 *malariae*).

The author concludes as follows —

“—— A dosage of 300 mg given as a single dose was successful in resolving the clinical attack in 3 days in 81 to 87 per cent of cases in all types of infection both as regards fever and parasites”

Parasitic relapses occurred after this treatment in all three infections

iii This trial was conducted at the Carmichael Medical College, Calcutta, on 20 patients suffering from clinical malaria with parasitaemia (10 *falciparum*, 6 *vivax*, and 4 mixed infections) These had had no antimalarial treatment for at least 6 weeks prior to treatment with paludrine The dosage employed in 6 cases (4 *falciparum*, and 2 *vivax*) was a single one of 100 mgm, and in the others 100 to 200 mgm daily for 2 to 5 days

The author gives the following summary —

“—— paludrine is a safe drug to use and will stop clinical attacks of malaria in doses which produce no untoward symptoms In the above series a minimum single dose of 100 mg, and a maximum of 700 mg, in five days were required to make the patient fever free and parasite free It had little effect on the sexual forms of the parasite ——”

iv This study was made at the Medical College Hospital, Calcutta, on 58 cases of malaria (20 *falciparum* and 38 *vivax*), with parasitaemia These were treated in 5 groups with doses of paludrine ranging from 600 mgm daily for 2 days followed by 300 mgm daily for 5-6 days [total 3,000 mgm] down to 200 mgm daily for 2 days only All were free of parasites by the 96th hour of treatment, but the pyrexia persisted in some cases beyond this, and was usually evident for a day or two after the blood had become negative

The author considers the drug “an excellent and effective remedy”, and thinks dosage must be continued after the peripheral blood is clear of parasites as the fever persists after this

vi This study was undertaken in two isolated areas under the control of the Assam Railway and Trading Co, Ltd The experiment was to determine (1) a satisfactory suppressive dosage of paludrine in those not suffering from acute malaria, and (2) the dosage necessary to control an acute attack of the disease In the first trial, a dose of 100 mgm of paludrine once a week was given as a prophylactic to 1,678 persons 294 others untreated served as controls This dosage for various reasons was not found adequate, so 100 mgm of paludrine was then given twice weekly to 1,075, and 200 mgm once weekly to 800 persons, 246 remained untreated as controls Two hundred and thirty-five acute attacks of malaria (152 *falciparum*, 61 *vivax*, 15 *falciparum* + *vivax*, and 7 *malariae*) were treated with single doses of 100 mgm or of 300 mgm of paludrine, or with 200 mgm daily for two days

The author reaches the following conclusions —

“1 As a suppressive, one tablet (100 mg) of paludrine once a week would probably be adequate, but when dealing with mass administration to a disinterested population a certain number are bound to miss the weekly dose for one reason or another One tablet (100 mg) twice a week reduces the chances of any one going a full fortnight without the tablet

“2 The success of suppressive measures is directly proportional to the efficiency of the administrative controls

"3. Three tablets (300 mg.) of paludrine will terminate a clinical attack and is as satisfactory from this point of view as two tablets (300 mg.) b.d. for two days."

vi. In the above series of papers are recorded the results of trials of paludrine in the field under varying conditions of life and of malarial endemicity in sundry parts of India and of Assam. These trials were conducted by independent workers at the request of the Malaria Institute of India, Delhi. In this paper Lt. Col. Afridi, Director of the Institute collates and analyses the data contained in them.

After a consideration of the characteristics of paludrine based on the reports of the original workers on the drug the author outlines the aim of the inquiry which briefly was to determine whether paludrine was effective against local strains of the malaria parasites (1) as a cure for clinical malaria, (2) as a radical cure of the infections, and (3) as a causal prophylactic or as a suppressive. The trials were conducted in rural dispensaries, in hospitals, in jails, and in tea estates and collieries—details of these are analysed. On the whole acute *falciparum* infections responded more rapidly to treatment than did *tertian*; there was some doubt about the response of *malariae* which the author believes on occasions to be delayed.

He concludes with the following summary—

1. Field trials on paludrine for the treatment of malaria were initiated in July, 1946 in different parts of India under the direction of the Malaria Institute of India. The tests were carried out under varying conditions such as rural dispensaries, hospitals, jails, tea estates and collieries. The result obtained up to December 1946 are analysed and reviewed critically.

"2. The value of different dosage regimes was assessed on 1,961 microscopically diagnosed cases of malaria of which 1,223 were *falciparum* (malignant tertian) malaria, 481 were *tertian* (benign tertian) malaria, 88 were *malariae* (quartan) malaria while the remaining 59 cases showed mixed infections.

"3. Paludrine was found to be as effective against the strains of malaria parasites in India as those tested elsewhere.

"4. A single dose of 0.1 gm. and 0.3 gm. of paludrine effected a clinical cure within three days in 84.1 and 89 per cent. of cases. The drug was equally effective against the three species of malaria parasites although the response was more rapid in malignant tertian than in benign tertian or quartan. In trials where paludrine and mepracrine were tested side by side the curative action of paludrine in the above doses was equal to that of mepracrine in daily dose of 0.3 and 0.4 gm. for 3 and 4 days respectively.

"5. Neither the prolongation of treatment up to 10 days nor an increase in the dosage of paludrine to 0.6 gm. per day caused any appreciable improvement in the percentage of clinical cure. The re-admission rates caused by relapses and/or reinfections were relatively lower in cases treated with high dosages but none of the regimes tested appeared to effect a complete cure. A follow-up treatment of 0.1 gm. once or twice weekly prevented the recurrence of disease in chronic relapsing cases.

"6. It is suggested that in the present state of our knowledge the most desirable course of treatment for malaria in India both in the dispensaries and the hospitals would be a single dose of 0.3 gm. of paludrine. In majority of cases relapses should be treated as and when they arise but for those who can be relied upon to take the drug regularly a follow-up treatment of 0.1 gm. once or twice a week should be prescribed for a minimum period of six months.

"7. Paludrine proved to be a safe drug, free from unpleasant effect and non-toxic even in high doses of 0.6 gm. per day. Patients placed on the drug experienced a feeling of well-being within an hour or two of taking it. It was well tolerated by infants and pregnant women.

began on the 1st June 1946 and was continued to 25th November. Anophelines were very numerous after abundant winter and spring rainfall. The number of persons receiving suppressive drugs was 1,347, controls numbered 885. Of those given suppressive treatment, 331 received 0.3 gm. quinacrine (mepacrine) once a week, 312 were given 0.3 gm. nivaquine C (dihydrochloride) once a week, 166 were given 0.3 gm. nivaquine M (methylen bis-oxynaphthoate) twice a week, 129 received 0.3 gm. nivaquine M once a week, 31 received 0.1 gm. nivaquine M daily, 182 were given 0.3 gm. nivaquine C twice a week, 196 were given 0.1 gm. nivaquine C daily. All these doses were for adults only.

The results given by the two salts of nivaquine were comparable in every respect, but in view of the superiority of nivaquine C over nivaquine M in the treatment of malaria attacks the latter preparation might well be dispensed with. With a dose of 0.3 gm. once a week, the suppressive results obtained with nivaquine are in every respect as good as those obtained with the same dose of mepacrine. Nivaquine C, 0.1 gm. daily, gave remarkable results, the parasite index was reduced to zero whereas in an exactly comparable control area the parasite index rose from 4.65 to 10.98 per cent. Among the 84 persons in this control area there were 29 confirmed cases of malaria, there were none among the 196 taking a daily dose of nivaquine C. In no case was there any symptom of intolerance to nivaquine, in this respect the drug is certainly superior to mepacrine, nivaquine does not discolour the skin.

McCULLOCH, R. N. & WATERHOUSE, D. F. **Laboratory and Field Tests of Mosquito Repellents**. Commonwealth of Australia Council for Sci. & Indust. Res. Bull. No 213. 28 pp. 1947. Melbourne.

The experiments were made during the recent war to find the best available mosquito repellent material for the fighting services exposed to malaria. Laboratory tests were conducted with the use of a tent containing large numbers of *Aedes notoscriptus* and *Aedes alboannulatus*. Other tests were made in cages with *Aedes aegypti* after a number of culicine species had been investigated for suitability. In the tent 1,000–2,000 adult mosquitoes were maintained, about 100 or so of which might attempt to bite at any time. The mosquito attack was severest at low levels, round the legs and ankles. Tent tests were presumed to be more like natural conditions but owing to the possible accumulation of vapour, only one or two materials could be tested in the tent per day. This involved the use of large numbers of insects. The cage tests employed much smaller numbers (100 or so), only an exposed arm surface was used. In both types of test, the time to first bite was considered very important but the intervals of subsequent bites were also considered in evaluating the repellents.

Field tests were done in New South Wales in coastal bush areas where *Aedes vigilax* was very common in places (biting untreated limbs at the rate of 25–50 per minute). Other tests were done in New Guinea where *Anopheles punctulatus farauti* and various culicines were the predominant biters.

The tests were made on more than 125 substances and some were tested at several dilutions. The most effective repellents giving nearly complete protection for 45 to 60 minutes under the most severe conditions, were Dimethyl phthalate, 612 (2-ethyl-1,3-hexane-diol), "Stayway" (diethylene glycol monobutyl ether acetate, etc.), oils of *Dacrydium franklinii* (Huon pine), *Melaleuca bracteata*, *Zieria smithii*, and *Backhousia myrtifolia*. Under similar conditions, Ceylon citronella oil gave protection for no more than twenty minutes.

CRUICK B. JR. WHORTON C. M. JONES R. JR., PULLMAN T. V. ALVING
A. S. EICHELBERGER, Lillian & ROYMAN S. A Lichen-Planus-Like
Eruption occurring during the Course of Chloroquine Administration. /
Clinical Investigation. 1948, May & 27 No. 3 Pt. 2, 56-9 4 figs. [10 refs.]

Of 30 healthy volunteers who were given chloroquine for one year in a dosage in excess of that required for antimalarial suppression two developed cutaneous eruptions simulating the rash occasionally caused by quinine. The patients had no serious systemic symptoms and the eruptions disappeared promptly when the drug was discontinued.

Three months after the end of chloroquine administration the drug was readministered to Case 1 at a dose of 0.3 gram a day for 17 days without reappearance of the eruption. Two months after the termination of the chronic toxicity study Case 2 resumed taking chloroquine in a dose of 0.3 gram twice a week. No cutaneous eruption developed in six months drug administration.

SCHNEIDER, J. DIGMAT M. VORON & SFAR M. Prophylaxie collective du paludisme par la premaline dans la région de Gabès (mai novembre 1948)
[Mass Prophylaxis of Malaria with Premaline in the Gabes Area, May to November 1948.] *Bull. Soc. Path. Exot.* 1948 v 41 Nos. 3 & 4 194-8

Malaria had been particularly severe in the Gabes region of Tunisia in 1944 and 1945. The outbreak of *P. falciparum* malaria in the latter year was very serious. Very few of the inhabitants either European or indigenous escaped malaria in 1945. The appearance of numerous new breeding places for *An. phlebotomus* and the extension of old breeding grounds were responsible for excessive mosquito prevalence. Pending the execution of large-scale anti-larval work it was decided to give suppressive treatment with premaline to the whole population numbering 3,580. Treatment was begun on the 1st May 1948. Of the confirmed cases on that date 67 in number were adequately treated. Each subject received premaline 3 tablets for adults, once a week during the first month and thereafter every ten days till the end of November. [One tablet of premaline contains quinine 0.1 gm., chloroquine 0.005 gm. and procaine 0.005 gm.] See DEPOUX *et al.* in this *Bullet.* 1938 v 33 508. The results were satisfactory. The spleen index of children fell from 33-27 to 17.7 per cent and of adults from 10.77 to 8.5 per cent during the period of drug administration. The fall in the parasite rates was from 14.1 to 0.61 per cent in children and from 8.97 to 1.25 per cent in adults. The total number of confirmed cases of malaria during the whole season was but 77. 10 of these were in the Kertana area where numerous nomads who had arrived for the date harvest escaped prophylactic treatment.

There was not the least evidence of intolerance to the drug, among the 32,880 treated. Anopheles was at least as intense as it had been during the previous year when malaria was severely epidemic. Norman H. Kirk

[Mass Prophylaxis of Malaria with Nivaquine. Results of Experience in Ghardimaou, Tunisia.] *Bull. Soc. Path. Exot.* 1948 v 41 Nos. 3 & 4 188-91

This paper gives the results of mass clinical prophylaxis of malaria with nivaquine a synthetic product formerly named sintonine. This *Bullet.* 1948 v 43 148. The experiment was carried out in the region of Ghardimaou Tunisia, where the population lives in small but stable scattered groups, farms or encampments, and is easy to keep under observation. Drug administration

TETZLAFF, F **Operation of the United States Public Health Service Malaria Control Program** *Pub Health Rep* Wash 1948, Apr 30, v 63, No 18, 557-63, 2 figs

Before the war in some States of the U S A no malaria control organization existed, any activity in this direction forming part of the general sanitation programme. The wide extension of control measures during the war years by the Public Health Service of the Central Government to protect military personnel resulted in a more general recognition by the public of the value of these measures. Towards the end of the war, the application of DDT as a residual insecticide to control *A. quadrimaculatus* proved to be so effective that this method became the sole measure of control in many areas with the cessation of the older methods of drainage and use of larvicides.

After the war the situation of the war years was reversed in that it became necessary to protect the civilian population from malaria introduced by returning servicemen. Residual DDT spray operations have been extended to cover all affected areas in the United States. Coincident fly control has been a major factor in the general acceptance and success of the method. It is hoped that the expense entailed will be accepted eventually as a local charge on the rates, the end result should be a reduction in malaria incidence to the extent that malaria will no longer constitute a significant health problem in the United States. Lastly State and local Health Departments have become familiar with the programme necessary for the control of any insects having a public health significance.

R Ford Tredre

CORRADETTI, A **Bases experimentales para la eliminacion de la malaria en la Costa del Peru** [**Experimental Basis of Malaria Control on the Coast of Peru**] Publicaciones de la Dirección General de Salud Publica Departamento de Malaria. 1947, Aug 7, 14 pp 2 graphs

The author describes the use of domestic spraying with DDT as a measure for the reduction of *Anopheles pseudopunctipennis* and malaria in the coastal plain of Peru.

It is known that in the coastal plain *A. punctipennis* is the principal vector it is only important when present in considerable numbers. The work was carried out in the valley of Mala, an area in which the Rockefeller Foundation has been studying malaria and applying other measures of control from 1942-46. The area was therefore a very suitable one for the experiment. DDT in kerosene was sprayed on walls of all houses in the valley at the rate of 2 gm per sq metre (apparently on a single occasion). The total human population of the area was 8,365. The Rockefeller Foundation had previously established that at the end of the transmission season the parasite rate was between 11 and 28.9 per cent. After the application of the DDT, the figure was always below 1 per cent at the same time of year. The greater part of the malaria was due to *P. vivax* but *P. falciparum* and *malariae* also occurred. All three were very greatly reduced by the DDT.

The author states in somewhat general terms that the distribution of the DDT has been followed by a general reduction of mortality due to infectious diseases. He discusses the use of similar methods for the destruction of *Phlebotomus* and the control of verruga peruana.

P A Buxton

J NATIONAL MALARIA Soc 1948 June v 7 No 2 157-65 **Cost Records in Malaria Control** Report of the Committee on Sanitary Engineering [HENDERSON J M, Chairman]

The vegetable oils were rather unsatisfactory because they were inclined to be irritant to the skin. *Blackhouse* and *Zurris* also have a pungent odour. "Stayway" is believed, on the basis of unpublished American work, to have a slight risk of toxicity danger to man. 612 has a distinct smell though in other respects is as good as dimethyl phthalate which was finally considered to be the best all round repellent.

Dimethyl phthalate is colourless, odourless and, apart from slight temporary smarting on application, is harmless to the skin. (Many thousands of men in the army have applied it for many months, often twice nightly without contracting dermatitis.) DMP was definitely better than most other phthalates (ethyl and butyl) tested, though a mixed methyl-ethyl phthalate was nearly as good. The treatment of clothing with dimethyl phthalate prevented mosquitoes biting through it for two or three days.

J. R. BULLING

BERNBERMAN D. A. The Use of DDT Residual Spray in Malaria Control and its Effect on General Sanitation in Rural Districts. *J. Palestine Lib Med Ass* 1948 Mar v 3 No. 3 49-61 1 map.

Two experiments were conducted in Lebanon in the Bekaa Plain between the Lebanon and the Anti-Lebanon mountain ranges. The object of the first was to observe the effect of residual DDT spray on the morbidity rates of various infectious fevers in two similar villages, two kilometres apart. All houses in one village were treated in the spring of 1945 and 75 per cent. of the houses in the second village were sprayed in the spring of 1946. The period of study was September and October 1946.

Tabulated results show that in the first village the number of cases of typhoid fever fevers other than typhoid diarrhoea dysentery and conjunctivitis were 230 out of a population of 678 (34 per cent.) and in the second village 137 out of 687 (20 per cent.). The author's opinion is that there was no factor other than the DDT spraying to account for the lower morbidity rate in the more recently treated village (since the morbidity rates before spraying are not given there is no evidence to show that any alteration did in fact occur).

In the second experiment the object was to test the value of DDT residual spray in the control of malaria. Three highly malarious villages were selected. They are situated overlooking the plain and about a kilometre from the lake and a swampy area of Amik. *Anopheles sachsi* is the chief anopheline but *A. superpictus* is also found. Preliminary observations were made on the abundance of breeding in the swamp and lake and on the spleen indices of the villagers. Then 5 per cent. DDT in kerosene was sprayed on the surface of the lake and in the houses. In treating the lake the vegetation was left and no attempt was made to reach the centre. Six sprayings were applied between May and November at intervals of 3 to 5 weeks. Each treatment was followed by a reduction in the numbers of larvae and in the numbers of adults in the houses. The numbers of other insects also diminished to remarkable extent but no ill effects on *Gambusia* or other fish were noted.

The author gives the costs of the experiment and describes methods and apparatus. He is satisfied that 5 per cent. DDT in kerosene is an effective larvicide even without the removal of aquatic vegetation and that residual spraying of dwellings resulted in the destruction of the insects associated with the dissemination of malaria, dengue sandfly fever conjunctivitis, summer diarrhoea of children, dysenteries and enteric and in highly malarious areas resulted in the reduction of the rates of parents of the inhabitants within period of eight months.

H. S. LANE

TETZLAFF, F **Operation of the United States Public Health Service Malaria Control Program** *Pub Health Rep* Wash 1948, Apr 30, v 63, No 18, 557-63, 2 figs

Before the war in some States of the U S A no malaria control organization existed, any activity in this direction forming part of the general sanitation programme. The wide extension of control measures during the war years by the Public Health Service of the Central Government to protect military personnel resulted in a more general recognition by the public of the value of these measures. Towards the end of the war, the application of DDT as a residual insecticide to control *A. quadrimaculatus* proved to be so effective that this method became the sole measure of control in many areas with the cessation of the older methods of drainage and use of larvicides.

After the war the situation of the war years was reversed in that it became necessary to protect the civilian population from malaria introduced by returning servicemen. Residual DDT spray operations have been extended to cover all affected areas in the United States. Coincident fly control has been a major factor in the general acceptance and success of the method. It is hoped that the expense entailed will be accepted eventually as a local charge on the rates, the end result should be a reduction in malaria incidence to the extent that malaria will no longer constitute a significant health problem in the United States. Lastly State and local Health Departments have become familiar with the programme necessary for the control of any insects having a public health significance.

CORRADETTI, A **Bases experimentales para la eliminacion de la malaria en la Costa del Peru** [**Experimental Basis of Malaria Control on the Coast of Peru**] Publicaciones de la Dirección General de Salud Publica Departamento de Malaria 1947, Aug 7, 14 pp 2 graphs

The author describes the use of domestic spraying with DDT as a measure for the reduction of *Anopheles pseudopunctipennis* and malaria in the coastal plain of Peru.

It is known that in the coastal plain *A. punctipennis* is the principal vector it is only important when present in considerable numbers. The work was carried out in the valley of Mala, an area in which the Rockefeller Foundation has been studying malaria and applying other measures of control from 1942-46. The area was therefore a very suitable one for the experiment. DDT in kerosene was sprayed on walls of all houses in the valley at the rate of 2 gm per sq metre (apparently on a single occasion). The total human population of the area was 8,365. The Rockefeller Foundation had previously established that at the end of the transmission season the parasite rate was between 11 and 28.9 per cent. After the application of the DDT, the figure was always below 1 per cent at the same time of year. The greater part of the malaria was due to *P. vivax*, but *P. falciparum* and *malariae* also occurred. All three were very greatly reduced by the DDT.

The author states in somewhat general terms that the distribution of the DDT has been followed by a general reduction of mortality due to infectious diseases. He discusses the use of similar methods for the destruction of *Phlebotomus* and the control of verruga peruana.

P A Buxton

J NATIONAL MALARIA Soc 1948 June v 7, No 2 157-65 **Cost Records in Malaria Control** Report of the Committee on Sanitary Engineering [HENDERSON J M Chairman]

The vegetable oils were rather unsatisfactory because they were inclined to be irritant to the skin. *Baobab* and *Zurra* also have a pungent odour. "Stayway" is believed, on the basis of unpublished American work, to have a slight risk of toxicity danger to man. *612* has a distinct smell though in other respects is as good as dimethyl phthalate which was finally considered to be the best all round repellent.

Dimethyl phthalate is colourless, odourless and apart from slight temporary smarting on application, is harmless to the skin. (Many thousands of men in the army have applied it for many months, often twice nightly without contracting dermatitis.) DMP was definitely better than most other phthalates (ethyl and butyl) tested, though a mixed methyl-ethyl phthalate was nearly as good. The treatment of clothing with dimethyl phthalate prevented mosquitoes biting through it for two or three days.

BERNBERIAN D. A. The Use of DDT Residual Spray in Malaria Control and its Effect on General Sanitation in Rural Districts. *J. Palest. Arab. Med. Ass.* 1943, Mar. v. 3 No. 3 49-61 1 map.

Two experiments were conducted in Lebanon in the Beká Plain between the Lebanon and the Anti-Lebanon mountain ranges. The object of the first was to observe the effect of residual DDT spray on the morbidity rates of various infectious fevers in two similar villages, two kilometres apart. All houses in one village were treated in the spring of 1945 and 75 per cent of the houses in the second village were sprayed in the spring of 1946. The period of study was September and October 1946.

Tabulated results show that in the first village the number of cases of typhoid fever, fevers other than typhoid, diarrhoea, dysentery and conjunctivitis were 230 out of a population of 678 (34 per cent.) and in the second village 157 out of 687 (20 per cent.). The author's opinion is that there was no factor other than the DDT spraying to account for the lower morbidity rate in the more recently treated village (since the morbidity rates before spraying are not given) there is no evidence to show that any alteration did in fact occur.

In the second experiment, the object was to test the value of DDT residual spray in the control of malaria. Three highly malarious villages were selected. They are situated overlooking the plain and about 1 kilometre from the lake and swampy area of Amik. *Anopheles sacharovi* is the chief anopheline but *A. superpictus* is also found. Preliminary observations were made on the abundance of breeding in the swamp and lake and on the spleen indices of the villagers. Then 5 per cent. DDT in kerosene was sprayed on the surface of the lake and in the houses. In treating the lake the vegetation was left and no attempt was made to reach the centre. Six sprays were applied between May and November at intervals of 3 to 5 weeks. Each treatment was followed by a reduction in the number of larvae and in the numbers of adults in the houses. The numbers of other insects also diminished to a remarkable extent but no ill effects on *Gambusia* or other fish were noted.

The author gives the costs of the experiment and describes methods and apparatus. He is satisfied that 5 per cent DDT in kerosene is an effective larvicide even without the removal of aquatic vegetation and that residual spraying of dwellings resulted in the destruction of the insects associated with the dissemination of malaria, dengue, sandfly fever, conjunctivitis, summer diarrhoea of children, dysenteries and enteric and in a highly malarious area resulted in the reduction of the sizes of spleens of the inhabitants within a period of eight months.

SIMPSON, M L. Reproduction of the "3T" Strain of *Plasmodium cathamerium* in White Pekin Ducks. *Am J Hyg* 1948, May, v 47, No 3, 315-34, 10 figs [19 refs]

This is the report of an elaborate and carefully controlled series of experiments on the cycle of *P. cathamerium* in the duck which deserved more interesting results than were actually obtained. The parasite was introduced by blood inoculation into (a) young ducks (two weeks old), (b) mature ducks and (c) canaries, and the ensuing infections were studied and compared. There was the same degree of synchronicity of segmentation in all three groups, viz. between 4 p.m. and 10 p.m. in a regular 24-hour cycle, unaffected by artificial conditions of lighting and darkness. In all birds, later in the disease, the synchronicity became less punctual. In canaries, segmentation was even more exactly timed and tended to occur 4 hours earlier in the day. The parasite density was greatest in young ducks and in the group exposed to artificially regulated light. The average number of merozoites per schizont was the same in all the ducks and throughout the 5 days of the patent period of the infection. In canaries, the number of merozoites varied during the course of the disease, probably because the patent period was lengthy and gave time for fluctuations to become manifest.

Late passage infections in ducks gave rise to fewer gametocytes than the earlier ones (a 6-fold decrease), indicating that long residence in the duck inhibited their production.

BLACK R H. The Resorption of Haemoglobin by the Renal Tubules in Haemoglobinuria. *Ann Trop Med & Parasit* 1948, Apr, v 42, No 1, 90-94, 12 figs on 2 pls [20 refs]

In man and some animals, conditions associated with haemoglobinuria often show eosinophilic granules in the epithelial cells of the convoluted tubules of the kidney. Such granules give the staining reactions characteristic of haemoglobin and are released into the lumen when the cells degenerate. The author suggests that haemoglobin in the glomerular filtrate is absorbed by the tubule cells and its nature modified in some way.

TRYPANOSOMIASIS

GEIGY R. Beobachtungen an einer Zucht von *Glossina palpalis*. [A Note on a Culture of *Glossina palpalis*.] Reprinted from *Verhandlungen d. Schweiz. Naturforschenden Gesellschaft Zurich* 1946, pp 155-8.

The paper describes the maintenance of a culture of *Glossina palpalis* in Switzerland for a considerable period.

The author reviews what is known about the relation of *Glossina palpalis* to temperature. As it is established that at about 13°C the adult flies are quite torpid and capable of surviving unfed for 10-15 days, he decided to bring them

from the Congo to Switzerland in small gauze cages in an ice box. About 40 per cent. of the flies with which he started arrived alive, 22 males and 98 females reaching Basle. The original number has been increased to some extent by the importation of pupae but it seems that six generations were reared at the time of writing and that the number of flies was increasing. The insects were kept always at 26°C. and 83 per cent. relative humidity and were offered food daily on guinea-pigs. Under these conditions one individual fly lived as long as 207 days and one female deposited sixteen larvae. The interval between the emergence from the pupa and the birth of the first larva is twenty-two days and after that births occur almost regularly at ten-day intervals. The duration of the pupal stage is thirty-five days in the female and about two days longer in the male. P. A. B. Sloan

JACKSON, C. H. V. The Analysis of a Tsetse-Fly Population. III. In *E. genies* 1948 Apr. v. 14 Pt. 2, 91-103, 2 figs.

The author is concerned with the study and analysis of populations of *Glossina morsitans* at Hakoma, Tanganyika Territory. The main body of his material is derived from flies which were marked weekly for a long period and statistical deductions are here given from those results [see this *Bulletin* 1945 v. 4, 186]. But the author has used a number of other ingenious methods of study and endeavours to check results obtained with one method against those of another. The present paper is stated to be the last of its series in it Jackson brings together some previous work, modifies certain of his methods and sets down his conclusions. For technical details the reader must refer to the original paper. Here it is only possible to make a brief and general abstract.

The bulk of the paper deals with the author's methods of calculating the actual population of tsetse per square mile for which a new method is developed based on those individual flies which are marked and then recaptured more than once. He also recapitulates his work on the calculation of death rates and birth rates, subject on which he has developed a formula, assessing the errors of his estimates. His information on the disposal of individual flies is based not only on the familiar marking method but on unmarked flies introduced into a type of environment not unsuitable to *G. morsitans* though that species does not occur in it [see this *Bulletin* 1948 43-51]. The statistical work has revealed short term fluctuations in death rates and birth rates which cannot be associated with changes in climate and appears to depend on factors in the fly population. It seems that male *G. morsitans* are relatively inactive during the first ten weeks of life and that for that period their death rate may be lower than it is later. This inactivity which has only recently been discovered affects the shape of survival curves and the estimate of mean life time figure however still appears to be about four weeks for male flies. The fact that male flies are inactive early in life explains what has already been observed that if one estimates the age of a sample of wild flies by the wing, it overestimates figure which is higher than the estimation based on flies which are marked and recovered. The inactivity early in life has caused the author to make recalculation of his estimate of the whole male population his previous estimates have to be increased by about 1.4 times. P. J. Bush

HILL, R. R. The Protein Content of Cerebrospinal Fluid in Trypanosomiasis. *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948 Mar. v. 41 No. 5 641-4 [16 refs.]

The most commonly used routine methods of protein estimation for cerebrospinal fluid depend on measurement either of precipitability as in the Oxford and Cantabrigia tests, or of opacity in some so-called turbidimetric test. The

is wide variability in the limits of normality given by different workers, even where the same methods are used. This is illustrated by the following figures, culled at random from various authorities —

| Authors | Method | Normal C S F protein in mgm per 100 cc |
|--------------------------------|--------------------------------|--|
| MESTREZAT (1912) | Turbidimetric (Diaphanometric) | 13-20 |
| BUZZARD & GRENFIELD (1921) | " (Mestrezat) | -30 |
| GREY (1930) | " (Proteinometer) | -40 |
| HARRISON (1939) | " (Mestrezat) | 10-30 |
| KING (1945) | " (Sulphosalicylic) | 20-40 |
| STITT <i>et al</i> (1945) | " (Denis & Ayer) | 15-40 |
| PANTON & MARRACK (1945) | " (Sulphosalicylic) | 20-35 |
| HUTCHINSON & HUNTER (1934) | Precipitation (Aufrecht) | 20-35 |
| LEVINSON (1929) | " (Nissl s) | 13-47 |

| French Trypanosomiasis Service | " (Sicard & Cantaloube) | -22 |
| Author | Turbidimetric (proteinometer) | 20-30 (35) |

Hill has performed an experiment in which three observers were asked to examine a number of cerebrospinal fluids both by the proteinometer and by the Sicard and Cantaloube methods. The former method consistently gave protein values $1\frac{1}{2}$ to 2 times as great as the latter. Such a discrepancy would be very important where the proteinometer indicates 30 to 40 mgm per 100 cc, since according to SICARD and CANTALOUBE (*Bull et Mém Soc Méd Hôpît de Paris*, 1916, v 40, 481) this figure is grossly abnormal, and according to FAIRBAIRN [this *Bulletin*, 1934, v 31, 559] and SAUNDERS (personal communication) it has a bad prognosis in sleeping sickness, whereas according to GREY (*Arch Dis Childhood*, 1930, v 5, 187) and others, it is within normal limits, or perhaps, at the worst, at the upper limit of normal.

The author considers the Sicard and Cantaloube method to be the method of choice for routine work, since it gives a precipitate which lends itself to accurate measurement more readily than does opacity. Workers who refer to the protein content of cerebrospinal fluid should mention the method used.

[At the International Trypanosomiasis Conference at Brazzaville in February 1948, the recommendations of which are not yet published, it was concluded that the upper limits of the cell-count and total protein content of the cerebrospinal fluid within which a patient should be considered in the lymphatic-blood stage should be 3 cells per cmm and 0.025 gm protein per 100 cc, as estimated by the Sicard-Cantaloube method, that a more precise and, if possible, more rapid method for estimating total protein should be investigated, and that further investigation should be made into the exact composition of the cerebrospinal fluid in the normal African.]

SALEUN, G & CHASSAIN, J. Premiers essais de traitement de la trypanosomase humaine, par la pentamidine en Afrique Équatoriale Française [First Trials of Pentamidine against Sleeping Sickness in French Equatorial Africa] *Bull Soc Path Exot* 1948, v 41, Nos 1/2, 89-104.

This paper describes in detail the investigation of pentamidine for sleeping sickness, by a number of officers of the Institut Pasteur de Brazzaville and of

the recently established Service Central d'Hygiène M. b. l. e. et de Prophylaxie de l'A. E. F. See also TRIQUET and ARABOULT this *Bulletin* 1948, v. 45 313. The findings are in the main confirmatory of work already published from other quarters. The first trials in A. E. F. were carried out at the Pasteur Institute in 1945 when 2 mgm./kgm. [whether dihydrochloride or di-bethionate is not stated] administered intravenously each day for 8-10 days was found to be too toxic. Dose was then reduced to 1.25 mgm./kgm. for the first injection, 1.75 mgm. the next day, and 2 mgm. daily thereafter for the remainder of the course. Trials were then extended first to the "hypomeries" in various outlying districts, and finally to the itinerant treatment teams, where a disaster immediately occurred. The first three patients collapsed immediately after their first intravenous injection of 1 mgm./kgm. Two of these individuals recovered within 4 hours, but the third died after 7 minutes of coma and epileptiform convulsions. An error in the dosage actually administered cannot be excluded with certainty. Nevertheless it was decided to use only the intramuscular route of administration for ambulatory treatment in the future.

The toxic effects of treatment are described in great detail. As is well known the most common and most striking immediate effect is a considerable fall in blood-pressure occasionally associated with syncope. Transitory albuminuria occurred in only 3.7 per cent. of the cases treated. In only one instance was there the possibility that a significant degree of renal damage might have been due to the treatment. When the intramuscular route was used, toxic reactions were much less frequent and syncope never occurred, even when the dose was 3 mgm./kgm. It was found that pregnancy does not contraindicate the use of pentamidine (this is of interest in view of the statement not yet backed by much published evidence that propanilidine tends to produce abortion see VAN HOOFF this *Bulletin* 1947 v. 44 1048).

A treatment-course studied in many of the centres consisted of 8 daily injections, 8 days rest and then 8 daily injections again. When the first three intravenous doses were 1.0, 1.5 and 1.5 mgm./kgm. respectively it was sometimes 4 or 5 days before trypanosomes were no longer to be found, but where treatment was by 1.5 mgm./kgm. throughout it was nearly always the case that trypanosomes could no longer be seen on the day after the first injection. Where treatment began with the lower doses there was transient reappearance of trypanosomes between the 8th and the 11th injections in 4 of 84 cases. Where treatment was by 1.5 mgm./kgm. from the start this temporary reappearance of trypanosomes occurred in 1 of 61 cases. The authors therefore write that there is apparently a delayed period when relapse tends to occur (*à pointe de relapse*) during the actual course of treatment, which they say also characterizes the use of certain arsenicals.

In the first trials at the Pasteur Institute 16 of the 32 cases treated had advanced beyond the lymphatico-blood stage. All the other cases of this report to the number of 348 were in the lymphatico-blood stage. All were sterilized by the end of their treatment courses and were still well up to the limit of observation which in most cases, however, does not seem to have exceeded five months at the time of writing. There was a favourable response in all 128 cases which had previously proved to be refractory to other remedies such as sodium tartar emetic and various arsenicals. E. M. LOURIE

SIGES A. De quelques réactions au cours d'un traitement par la pentamidine.
Some Reactions during a course of Pentamidine Treatment. *Bul. Soc. Path. Exot.* 1948, v. 41, No. 3, 4 159-61

Mlle. W. R. aged 27 does not seem to have kindly tolerated treatment for very long sickness. She is apparently one of the two accidentally infected ladies about

whom SICÉ has already written, this *Bulletin*, 1948, v 45, 312] She was first treated by combined tartar emetic and atoxyl. This had to be stopped after a total of 250 mgm tartar emetic and 2.5 gm atoxyl, which caused pain along the veins chosen for injection, headache, and subjective visual disturbances. She then received suramin, first alone at a dosage of 1 gm, then in doses of 0.75 gm together with neo-stibosan. This gave rise to albuminuria, the appearance of leucocytes and blood casts in the urine, and hyperpyrexia. She was then given pentamidine isethionate in the gluteal regions, 150 mgm (i.e. 3 mgm per kgm body weight) daily. There was no particular reaction throughout the 8-day course of treatment, except for mild recrudescence of the renal disturbance. There was then a rest-period of 13 days, after which daily intramuscular injections were started again. At the 4th injection the patient developed a feeling of constriction in the throat, a bitter taste in the mouth, and a painful, tender, red swelling, about 5 cm in diameter and about 10 cm from the point of injection. It was freely movable under the skin. In the course of the next few days it assumed various colours and gradually subsided. Daily intramuscular treatment was, however, continued uninterruptedly in the scapular region without further complication, except for fleeting sensations of numbness down the limb on the side injected. The second treatment-course totalled 9 injections. [The tumour was non-fluctuant, but could it not have been a haematoma?] E M Lourie

TRINQUIER, E & PELLISSIER, A. Emploi du 3177 RP par voie buccale dans le traitement de la maladie du sommeil [Oral Treatment of Sleeping Sickness by 3177 RP] *Bull Soc Path Exot* 1948, v 41, Nos 3/4, 161-5

This report from the Brazzaville Pasteur Institute deals with the treatment of sleeping sickness by 2224 RP and 3177 RP, prepared by the Société Parisienne d'Expansion Chimique. [The compounds are identical, respectively, with melarsen (FRIEDHEIM, this *Bulletin*, 1941, v 38, 634) and melarsen oxide (WEINMAN and FRANZ, this *Bulletin*, 1946, v 43, 207, VAN HOOFF, this *Bulletin*, 1947, v 44, 1048)]

Treatment was given orally. The first patient, who was in the nervous stage of infection, developed profuse diarrhoea after 2 doses of 30 mgm. The standard course of 3177 RP adopted for subsequent cases, therefore, consisted of 14 daily doses, comprising 1 of 10 mgm, followed by 4 of 20 mgm, and then 9 of 30 mgm per adult, irrespective of body weight. This was well tolerated in the lymphatico-blood stage (3 cases) and in the stage of meningeal reaction (5 cases) but not in the meningo-encephalitic stage (2 cases). As a result of the slight evidence obtained on a follow-up period of only 1 month the authors conclude that 3177 RP has a very rapid sterilizing action, that it can probably cure most cases in the lymphatico-blood stage, that it has no action in the stage of meningeal reaction, and that it is dangerous in the meningo-encephalitic stage.

In an addendum, benefit is claimed for 3 early cases treated by 2224 RP, also administered orally. E M Lourie

TRINQUIER, E & PELLISSIER, A. Emploi du 2224 RP par voie buccale dans le traitement de la maladie du sommeil [Oral Treatment of Sleeping Sickness by 2224 RP] *Bull Soc Path Exot* 1948, v 41, Nos 3/4, 260-68

Compound 2224 RP is identical with FRIEDHEIM's melarsen [see above].

Treatment was given orally in all cases. As a result of earlier findings by FRIEDHEIM and by MURAZ, which the authors describe, and after several unfavourable experiences with other dosages, the course finally adopted consisted of daily treatment for 2 weeks, beginning with 20 mgm/kgm the

first day rising by 10 mgm./kgm. daily to 60 mgm./kgm. on the 5th day and maintained at this level for the remainder of the course but with a ceiling-dose of 3 gm. This was well supported in all the cases thus treated.

The gland-juce or blood was usually cleared of trypanosomes within 24 hours, but sometimes not until the fourth day. Symptoms rapidly abated in earlier cases, but sometimes became aggravated in the later stages of infection.

Cases treated consisted of 1 in the lymphatic-blood stage, 1 in the stage of meningeal reaction and 18 in the stage of meningo-encephalitis, 10 of which had proved resistant to earlier treatment with other compounds. The records given include results of cerebrospinal fluid examinations at the beginning at the end and 1 month after the end of treatment. The case in the lymphatic-blood stage responded well, and was still well 1 month after a single course of treatment but this was judged to be inadequate for the other types of case.

E. M. Lewis

SALAT G. & CRASSAUX J. Essai de chimio-prophylaxie de la trypanosomiose humaine en Afrique Equatoriale Française par la pentamidine. [Chemo-prophylaxis of Sleeping Sickness by Pentamidine in French Equatorial Africa.] *Bull. Soc. Path. Exot.* 1948, v 41 Nos. 3/4 163-8.

The authors report preliminary results of an experiment by CUOCUARA and SOUVIAT in the Ouhanghi-Chari district of French Equatorial Africa.

On June 18th, 1946, the 409 inhabitants of 3 villages were examined 144 of these persons were already under observation after previous treatment for sleeping sickness, and 4 new cases were discovered. The remaining 261 persons were given a single intramuscular injection of pentamidine 4 mgm./kgm. for children (5-1 years, and 5 mgm./kgm. for those over 12 years of age.

The results of examinations at quarterly intervals, before and after this treatment were as follows —

| Time of examination | | New cases | Index of new cases |
|---------------------|------------------|-----------|--------------------|
| | | | Per cent |
| Before treatment | 1st quarter 1945 | 28 | 4.7 |
| | 2nd | 20 | 4.8 |
| | 3rd | 4 | 1.09 |
| | 4th | 10 | 3.2 |
| | 1st 1946 | 13 | 4.06 |
| | 2nd " | 12 | 3.8 |
| After treatment | 3rd quarter 1946 | 2 | 0.9 |
| | 4th | 0 | 0 |
| | Jan Feb 1947 | 0 | 0 |

The authors therefore believe that single injection of pentamidine can protect for 6 to 8 months.

[The Index of New Cases is calculated as follows according to the International Trypanosomiasis Conference at Brazzaville February 1948 —

Total new cases 100

Total examined, less old cases considered not cured

E. M. Lewis

- 1 LAUNOY, L & JEANPIERRE, C Essais sur l'action préventive du diamidino-diphénolypentane administré per os sur la trypanosomose expérimentale à *Trypanosoma equiperdum* du rat [Prophylactic Action of Oral Pentamidine against *T. equiperdum* Infection in the Rat] *Bull Soc Path Exot* 1948, v 41, Nos 1/2, 25-8
- ii — & — Suite à l'étude de l'action préventive du diamidino-diphénolypentane administré per os, sur la trypanosomose expérimentale à *Trypanosoma equiperdum* du rat [Further Studies of the Prophylactic Action of Oral Pentamidine in the Rat] *Ibid* v 41, Nos 3/4, 168-72

1 Thirty-six rats were given a single dose of pentamidine orally, over a dosage-range of 5 to 15 mgm per 100 gm body weight. There were 8 deaths from toxic action in the range 7.5-15 mgm, though most of the rats treated with 10 mgm withstood this amount. Each of the survivors received a single subcutaneous inoculation of 1 million *T. equiperdum* at intervals ranging from 5 to 20 days after treatment. The protective effects appeared in somewhat irregular manner. Complete protection for 7 days may, however, be expected after an oral dose of 5 mgm/100 gm. This is 10 times greater than the dose capable of protecting 50 per cent of rats for 14 days after subcutaneous administration [LAUNOY and LAGODSKY, *Bull Soc Path Exot*, 1940, v 33, 320, and this *Bulletin*, 1947, v 44, 702].

The therapeutic effect of oral treatment was also investigated. In heavy infections, doses up to 20 mgm/100 gm cleared the blood temporarily but did not cure. In earlier, light infections, there were 3 cures among 10 animals treated with 10 mgm/100 gm.

[There are two small errors in the authors' references to earlier work. WEINMAN and FRANZ (this *Bulletin*, 1946, v 43, 207) worked with melarsen oxide, not melarsen, and CLAESSENS (this *Bulletin*, 1947, v 44, 49) reported on propamidine, not pentamidine.]

ii The main burden of this contribution is to reduce the authors' previous estimate (see i above) of pentamidine's prophylactic powers. Further experiments, under the same conditions as above, showed that an oral dose of 10 mgm/kgm confers complete protection for only 4 or 5 days in only about 15 per cent of rats treated. E M Lourie

LAUNOY L & CHABOUD G, Mlle Des actions curative et preventive du diamidino diphénolypentane sur les infections à *Trypanosoma equinum* [Curative and Prophylactic Action of Pentamidine in *T. equinum* Infections] *C R Soc Biol* 1948 Apr, v 142, Nos 7/8, 432-3

Details are given of experiments in which pentamidine was shown to exercise curative and prophylactic effects against *T. equinum* in mice, rats and guinea-pigs. The trypanosome strain had been obtained from the Oswaldo Cruz Institute, Rio de Janeiro, in June 1947 but its previous history is not given. E M Lourie

VACHAN JONES T G C A Short Survey of the Aims and Functions of the Game and Tsetse Control Department of Northern Rhodesia. Reprinted from *Rhodesia's Game and Tsetse* 1948, 12 pp

The author gives a general readable account of problems of game pests and fisheries and of the method which is being developed by the Government of Northern Rhodesia for handling them. The author is Director of the Department of Game and Tsetse Control in that territory.

The subject is in itself very complex for in one place game may be an asset, in another a liability—so that there are conflicting interests between conservation and development of the territory or between the sportsman or the protectionist on one side and the pastoral or agricultural African on the other. Moreover different methods of studying the problems and dealing with them have been developed in different territories on the eastern side of Africa. It is certainly clear that it is wise to consider the whole of the wild life as a related group of problems and that these are important economically, particularly in this large territory with a sparse population of people who are dependent to a great extent on food which they can themselves obtain or produce.

The Government of Northern Rhodesia started well by establishing the facts. They obtained the services of C. R. S. Pitman who produced a faunal survey published in 1934. In it he not only set down a mass of information about the animals and their distribution in the territory, but he also defined the main problems and suggested methods for their solution based on his own long experience in Uganda. Some of the immediate obvious problems are the control of elephant and of the ivory trade and development of what is required by the tourist and the sportsman—also the control of game in areas where it competes with cattle—the destruction of tsetse and the development of fisheries. The author in his position of Director of the Game and Tsetse Department of the territory has endeavoured to develop a unified view of these biological problems and a unified way of dealing with them. Here he has met with success partly it is believed because of his experience in administration in this country.

Two problems are of immediate concern to the readers of this Bulletin. The first is tsetse mainly *C. morsitans*. The policy of the Department has been to take the disease methods developed by neighbouring countries north and south and to make use of game exclusion or destruction and also of select clearing in places where there were urgent tsetse problems. As two methods have been used it is not possible to state which is most effective but the general results are empirically encouraging. The second problem is the risk of spread of rinderpest from Tanganyika and countries to the north into the Rhodesias. This was met partly by control of movement of cattle but also by destruction of game along a line which was approximately the southern frontier of the distribution of the disease.

The general tone of the paper is discreetly optimistic. One receives an impression that the author has thought very carefully about his group of problems, that some success has been won against the tsetse and that the prospect of adding wealth to the country directly or indirectly is considerable.

TOMIE, Eleanor J. & REYS, C. W. The Cultivation of *Trypanosoma cruzi* in Dialysate Medium. Research Notes. J. Parasitol. 1948, 34, No. 162-3, 1 fig.

This note describes a medium prepared in loops of Cellophane tubing, suspended, then in the overlay of diphase blood agar medium which is used for the routine cultivation of the organism. The stock medium consists of a blood agar made essentially as recommended by DE FAJON (this Bulletin 1944, 41, 348), slant of this are overlaid with an equal quantity (10 cc.) of Loew's solution. For details of preparation and an illustration of the loop method the original paper should be consulted.

It is stated that *Trypanosoma cruzi* has been maintained in the dialysate medium for more than 3 years at temperature of 4–5°C. Bi-weekly serial transfers have been made from an inoculum of about one cc. of loop fluid containing active organisms. Growth has been good and the virulence of the organisms has not decreased.

It is concluded that *T. cruzi* may thus be grown without proteins or other non-dialysable substances

SEN GUPTA, P C Observations on an Outbreak of Kala-Azar in Calcutta *Indian Med Gaz* 1947, Dec, v 82, No 12, 726-34, 5 graphs and 3 maps [10 refs]

In 1921 a kala azar out-patient clinic was opened at the Calcutta School of Tropical Medicine at this clinic data were collected which led to the observation by KNOWLES, NAPIER and DAS GUPTA in 1923 [this *Bulletin* 1923 v 20, 866] that kala azar was highly endemic in one quarter in Calcutta, whereas much of the town was comparatively free of infection. Intensive investigation in this quarter by these workers led to the first incrimination of the sandfly *Phlebotomus argentipes*, which subsequent investigation, culminating in the work of SWAMINATH, SHORTT and ANDERSON [*ibid*, 1943, v 40, 227] showed to be the vector.

This clinic has continued to operate, and in the years following the Bengal famine of 1943 an increase in the numbers and in the severity of the cases of kala azar was noted. Records of attendance of fresh cases show a rise to a high plateau in the years 1923, 1924 and 1925 (over 1,100 cases) with a gradual fall to 1930 (236 cases) and another increase in 1944 which culminated in a very sharp rise at the beginning of 1946. Distribution maps of indigenous cases in 1922-23 and 1942-43, respectively, show that little change occurred, but in 1946, although the old endemic area shows the greatest concentration of cases and the non-infected areas in the centre of the town are strikingly free still, there is a tendency for a centrifugal spread to the suburban areas that adjoin the endemic area. The increase in the severity of the disease is reflected in the frequency of complications, e.g., from 1935 to 1939 the incidence of cancrum oris was 1.7 per cent and from 1943 to 1946 7.1 per cent, and 5 cases of agranulocytosis occurred in 1946 and the first half of 1947, whereas this complication was not observed in Indian cases before 1942.

The factors which led to this increase were, the author considers, (i) the famine of 1943, at its worst from August to November, which caused widespread economic distress especially among the poorer sections of the population, (ii) the increased incidence of other diseases, cholera, smallpox, typhoid and malaria (iii) the population factor, i.e., the presence of susceptible material in the form of children born since the last epidemic wave and possibly (iv) an increase in the virulence of the parasite. "The indications are that, by the passage through this devitalized and highly susceptible population, the virulence

of the parasite was enhanced and the epidemic was maintained and progressed to the peak even when most of the other epidemiological factors had ceased to operate."

CHANG N. C. & HOU T. C. Cold Hemagglutinin in Chinese Kala Azar. *Proc Soc. Exper. Biol. & Med.* 1948, May v 68, No. 1 7-4

Cold hemagglutinin in titers above 1:32 has been found in only 18.7% among 68 Chinese patients with kala azar. The highest titer obtained was 1:56. The titer bears no relationship to the severity, stage and treatment of the disease. Our results further suggest that there is no correlation between cold hemagglutinin titer and serum globulin content.

SEN GUPTA P. C., MALLIK K. N. B. & CHAKRAVARTY N. K. Observations on Pneumococcal Meningitis as a Complication of Kala-Azar. *Indian Med. Gaz.* 1948 Jan. v 83 No. 1 8-11 2 figs. on 1 pl.

The only reference to pneumococcal meningitis as a complication of kala azar that the authors were able to find was a statement by Rogers in his *Fever in the Tropics* (1919) that he found two instances in a series of 40 post mortem examinations in cases of kala azar.

The authors report four cases of kala azar in which a fatal pneumococcal meningitis occurred. The cases were encountered during the period of increased endemicity and increased severity of kala azar in Calcutta that followed the Bengal famine of 1943. All the patients were severely ill prior to the development of this fatal complication. In one case it was secondary to pneumonia, in one to cancerum oris, and in one to otitis media. In the fourth case no other focus was detected. All four patients were severely anaemic (haemoglobin 4.67 to 6.18 gm. per 100 cc.) and all but one had marked leucopenia (1,000 to 2,000) the exception was the patient with pneumonia (24,000). The cerebrospinal fluid was under only slight pressure. It was slightly hazy and not purulent and there were only scanty pneumococci present.

The treatment given was penicillin intrathecally and intramuscularly. There was no response, and the fatal issue—within 24 to 36 hours of onset of symptoms—was not postponed. It was considered that the leucopenia explained the relatively low cell counts in the cerebrospinal fluid and the rapid course of the disease.

GHOSH, S. M. & SINHA N. K. Trial of Pentamidine Isothionate in Kala-Azar Cases in the Patna Medical College Hospital (Preliminary Report). *Indian Med. Gaz.* 1948 Jan. v 83 No. 1 11-14

Treatment by pentamidine methosulphate was undertaken in 10 cases of kala azar in 10 of which the diagnosis had been made by the Giemsa film and in the 1st spinal puncture smear. In the remainder the diagnosis was by the slide-culture test which was positive in every case.

The injections were given on alternate days intramuscularly. The first dose was 1 ml. the second 1.5 ml. and the third 1.5 ml. volume of a 10% solution. The weight of the patient was about 100 lb. so that the maximum dose was 15 mgm. per day.

The results were judged on clinical basis. The temperature fell to normal after 5 to 6 days and by 6 days the leucocytes had begun to be diminished. The platelet count and the haemoglobin level were normal in 16 patients. The red cell count began to rise and it has never fallen from the value that it reached 10 days after the start of treatment.

improvement is recorded, no red cell count was over 4,100,000 and in 8 cases it is given as below 3,000,000 [There are no records of leucocyte counts]

The authors state that "No relapse was found in any of the cases so far observed" [They do not state if there was any form of follow-up of cases. In the paper there is no evidence that any case was followed for more than a few weeks after completion of treatment. However, this paper is called a preliminary report, so that further information may be given later]

There is no record of any ill-effects except bleeding from the needle track which was apparently troublesome in a few cases [In the title and the text isethionate is spelt "isothionate"] L E Napier

RANQUE, J, RANQUE, M, CABASSU, J & CABASSU, H *Le diagnostic precoce de la leishmaniose canine par la ponction ganglionnaire. Reflexions à propos de soixante examens positifs obtenus en dix mois dans la region marseillaise* [The Early Diagnosis of Canine Leishmaniasis by Gland Puncture 60 Positive Results in Ten Months in the Marseilles Region] *Bull Acad Nat Méd* 1948, v 112, Nos 19/20, 339-40

Gland puncture in dogs can be carried out on a large scale, it is easy to perform, is acceptable to dog-owners, gives a satisfactory percentage of positive results and allows a very early diagnosis of canine leishmaniasis to be made before the clinical manifestations are clear

In 94 dogs examined in the Marseilles area in 10 months, only 40 were clinically suspicious of leishmaniasis, and 6 were completely asymptomatic. Gland puncture revealed 60 positive, 29 negative and 5 doubtful results. In 46 formol reactions carried out in parallel, only 15 were frankly positive, 30 were negative and one was doubtful. In two dogs, leishmania were found in skin smears and in four others they were found at autopsy in the bone marrow, liver and spleen. The full results will be published later, but the authors make the following observations —

(1) Gland puncture gives the most significant results in the early stages of the disease, before the formal reaction or the clinical features are diagnostic

(2) When the disease is established, the furfuraceous dermatitis and the positive formol reaction make the diagnosis simple but leishmania are far fewer in the glands and prolonged search may be required before they are found if gland punctures are persistently negative, resort is had to smears from the skin, marrow, liver or spleen

(3) In the final stages, the leishmania seem to be lysed in the glands, liver and spleen, but persist intact in the bone marrow in large numbers

(4) In 20 cases, where a particularly early diagnosis was made by gland puncture, in the absence of any suspicious skin lesion, antimony treatment suddenly resulted in the appearance of the characteristic furfuraceous dermatitis and a spontaneous deterioration in the general condition this new phenomenon is regarded as being analogous to the Herxheimer reaction in syphilis

(5) Gland puncture has a prophylactic value, as it allows serial diagnoses to be made at the earliest stages when the disease is probably most contagious

(6) Canine leishmaniasis is still as endemic around Marseilles as it was when PRINGAULT described it in 1914 [this *Bulletin*, 1914, v 4, 398]

BOLLIGER, A & BACKHOUSE, T C *Transmission of Kala-Azar to the Australian Marsupials *Trichosurus vulpecula* and *Pseudocheirus lamginosus** *Trans Roy Soc Trop Med & Hyg* 1948, May, v 41, No 6, 797-814, 14 figs on 4 pls [13 refs]

In an earlier paper ARMYTAGE & BOLLIGER [this *Bulletin*, 1945, v 42, 358] reported on their successful inoculation of *Leishmania donovani* to the pouch

young of the common Australian possum (*Trichosurus vulpecula*). In the present paper a full account of further experiments with twenty four possums and one ring-tailed possum (*Pseudochirus lunatus*) is given. Twenty three of the twenty five animals including the ring tailed possum, became definitely infected. The animals were of all ages. Pouched young remained longer in the pouch up to 6 months instead of the usual 3 or 4 months, and showed stunted growth and fine grey woolly fur. The time of survival varied from 81 to 704 days. Some of the larger animals which survived infection for over a year showed no immediate effects of the infection for several months apart from a transient conjunctivitis and other eye changes. Loss of weight or failure of the growing animal to increase normally was one of the earlier signs of infection. The fur changed to a fine woolly structure. Occasionally necrotic skin lesions appeared temporarily near the root of the tail.

In the majority of possums serious eye changes occurred. Apart from the conjunctivitis, which cleared up after a few weeks or months the eye became hazy and iritis developed. The haziness was due to small whitish dots adhering to the posterior aspect of the cornea. Increasing keratitis giving the cornea a bluish-white opaque appearance might seriously or completely impair the sight. The iris showed a tendency to adhere to the lens. In some cases corneal abrasions, scars and haemorrhage into the iris were noted.

Advanced kala azar produces marked degeneration of the testes. This is manifest by diminution in size and alteration in spermatogenesis. The testes may be only a half or a third of their normal size while abnormal spermatozoa are produced or complete cessation of spermatogenesis may occur. In the majority of females, the pouch and mammary glands are found to atrophy. The pituitary and suprarenals were generally smaller than normal and frequently contained parasites so that the genital atrophy and stunted growth may have been caused by interference with the gonadotropins and growth hormones. In the brain and spinal cord the lesions take the form of a dense invasion of the pia-arachnoid with lymphoid cells, and perivascular infiltration in the cerebral cortex and grey matter of the cord. There is marked proliferation of adjuvant cells around the cortical capillaries and many of them include parasites. In most animals the spleen is enlarged but in three it was reduced in size. Generally the size of the liver fell within normal limits, though excessively large livers occurred as well as small ones. The kidneys appeared normal but in half the animals parasitized cells occurred. In one animal parasites occurred in cells of the renal tubules. Parasites were present in all the organs after the single injection intraperitoneally or intracardially. Blood from another infected animal of culture or of bone marrow from a human case.

It is evident that the Australian marsupial the possum, is highly susceptible to kala azar and will be a suitable animal for investigation of the disease in that country. The details of the history and histological findings in three of the cases are given while the appearance of the abdominal organs in two cases as shown in photographs and histological findings are illustrated by twelve micrographs.

C. M. S. YOUNG

HERTIG M. & FAIRCHILD G. B. The Control of *Phlebotomus* in Peru with DDT. *Am J Trop Med* 1948 Mar v 28, No. 3, 257-301 map & 4 figs on - 5 pl.

The authors, both of whom are authorities on the entomological side of the subject give an account of the control of *Phlebotomus* in Peru with DDT together with number of valuable notes on the biology of these insects.

Preliminary work in the Mediterranean had shown that spraying houses with DDT in kerosene results in a very great reduction in nuisance from sandflies and

in the number of specimens of *Phlebotomus* which can be caught, though there was no reduction in untreated buildings in the neighbourhood

The work here described was carried out in 1945 in Peru, a country in which *Phlebotomus* is of great importance as a vector of human disease. The authors worked in the Rimac Valley at a little over 6,000 ft in places where *Phlebotomus verrucarum* predominated. They estimated the number of these insects by catching them in houses, stables, poultry houses, caves and cavities in stone walls, driving them out with tobacco smoke and observing them with an electric torch. They also estimated their abundance by the number of the characteristic bites on human beings, and by reports about annoyance from these insects. They also appear to have placed considerable reliance on what they describe as the "Burro rate" - we are inclined to suppose that this must refer to the number of sandflies biting a donkey (*Equus asinus*).

The authors' standard application was a 5 per cent solution of DDT in kerosene sprayed at the rate of one gallon per thousand square feet on walls of houses, cavities in dry stone walls and so forth. The results are fully presented and discussed and are accompanied by photographs showing the type of building and of country, and plans showing which houses or walls were or were not sprayed in certain villages. It was found repeatedly that if a room or stable was adequately sprayed it was rare to find any sandflies or obtain any report of biting for several months - this, as the authors remark, would cover the whole sandfly season in many parts of the world. Even spraying the outside of a mud house is fairly effective and spraying the spaces in a dry stone wall is also effective. It seems then that with DDT applied in this way, one may not only suppose that a large number of sandflies are killed but one has a sort of barrier between the insect and the human inhabitants. The authors also point out that as the life cycle of *Phlebotomus* is long a sandfly population would only build itself up again very slowly after being greatly reduced by DDT [a point which one would like to see considered in relation to some population statistics]. As in other parts of the world, it was clear that the sandflies were flying a very short distance for they were discovered in numbers between 75 and 200 yards from the sprayed structures, provided suitable shelter was available. A point of interest in the present paper is that unlike much work on insecticides it pays very full attention to the biology of the insect.

The authors have also considered their results in relation to the spread of diseases transmitted by *Phlebotomus*. They controlled the insect in two large construction camps, and this was followed by an almost complete cessation of new cases of cutaneous leishmaniasis and bartonellosis.

GROENENDIJK H J Die *Rickettsia prowazeki* im bebrüteten Hühnerei [*Rickettsia prowazeki* in Egg Culture] *Ztschr f Hyg u Infektionskr* 1944 Nov 12 v 126 Nos 1/2 170-78

GIROUD P & CIACCIO G Valeur de divers extraits pulmonaires de lapin infecté de *Rickettsia prowazeki*, jugée par l'agglutination des rickettsies [The Estimation by *Rickettsia*-Agglutination Tests of the Potency of Various Extracts of the Lungs of Rabbits inoculated with *Rickettsia prowazeki*] *Bull Soc Path Exot* 1948, v 41, Nos 3/4, 117-20 [10 refs]

Soluble antigens were obtained from the lungs of rabbits infected with *Rickettsia prowazeki*, by extraction with ethyl alcohol, methyl alcohol, dilute glycerin, saline solutions, and distilled water

The potency of the extracts was tested by inoculating rabbits with them and afterwards estimating the titre of complement fixation tests carried out on the animals' serum.

The alcoholic extracts caused more rapid responses than the others, and when dehydrated *in vacuo* at -40°C . retained their full antigenic power for at least 30 days.

BIRLING R. & OELRICHS Lilly Untersuchungen über die Fleckfieberinfektion beim Kaninchen. [Investigation of Typhus-Fever Infection in Rabbits.] *Zschr f Hyg u Infektionskr* 1947 Jan. 6 v 177 Nos. 1/2, 13-28.

This is a study of the reaction described by GIBSON (this Bulletin 1938: 35-740) as resulting from the intracutaneous injection of typhus rickettsiae into rabbits.

After a series of careful experiments the authors concluded that the intensity of the reaction in strictly controlled conditions could serve as a measure of the antigenic potency of suspensions containing living rickettsiae and therefore also of the suitability of the suspensions for the preparation of vaccines. Vulture sac material was regarded as suitable when it caused a definite reaction in dilutions of 1:10,000 to 1:100,000. With fresh suspension the index (potency based on the reaction) was parallel with the richness of the suspensions in rickettsiae.

With killed suspensions very rich in rickettsiae an early mild reaction occurred owing to the presence of endotoxins; a similar reaction might also occur with living rickettsiae but in this case it was followed by the more severe reaction resulting from the multiplication of the rickettsiae in the skin.

John H. D. McGraw

BIRLING R. & OELRICHS Lilly Untersuchungen über aktive und passive Fleckfieberimmunität bei Kaninchen. [Investigation of Active and Passive Immunity against Typhus Fever in Rabbits.] *Zschr f Hyg u Infektionskr* 1947 Jan. 6 v 177 Nos. 1/2, 29-40.

Continuing their study of the Gibson reaction the authors found that a pronounced degree of active immunity against further intracutaneous inoculation with homologous rickettsiae was produced within seven days in rabbits which had been inoculated intracutaneously with large doses of vulture sac suspensions containing living rickettsiae.

An appreciable degree of immunity was also caused by injections of killed suspensions, but then the immunity was not pronounced and the occurrence of allergic reactions due to the vulture sac material was more marked. It follows that the reaction was not considered suitable for use in the practical testing of vaccines. Allergic reactions could however be prevented by using rickettsial suspensions of different origin for the second inoculation: for example lung suspensions obtained from rabbits after several lung passages of infection. By this procedure all trace of the original vulture sac material was removed.

The potency of rickettsial vaccines could be measured by finding the quantity of immune serum needed to prevent the occurrence of the Gibson reaction and then comparing this with the quantity of the same serum needed to prevent the reaction when a vaccine of known potency was employed in the same way.

John H. D. McGraw

SFORZA, M Sul contenuto in agglutinine normali Antiproteus OX19 e OX2 in individui residenti in Eritrea [Agglutinins against *Proteus* OX19 and OX2 normally occurring among Residents in Eritrea] *Boll Soc Ital di Med e Igiene Trop* (Sez Eritrea) 1947, v 7, Nos 5/6, 464-74 [11 refs] English summary (7 lines)

Weil-Felix tests were carried out on groups of healthy persons in Eritrea before and after the epidemic of 1946 Before the epidemic season the percentage of reactions against *Proteus* OX19 at titres of 1-160 and 1-320 were — Among Italians 1 17, hill-country natives 8 2, and lowland natives 6 7 After the epidemic the corresponding figures were 13 2, 21 7 and 18 9

Comparative tests with *Proteus* OX2 were carried out only during the post-epidemic season, titres higher than those observed with OX19 occurred in 17 per cent of the Italians, in 8 per cent of the hill-country natives and in 18 per cent of the lowland natives, so the reactions were mostly of the OX19 type

John W D Megaw

MORGAN, H R, NEVA, F A, FAHEY, R J & FINLAND, M Brill's Disease Report of Two serologically proved Cases of Typhus Fever in Irish-Born Residents of Boston *New England J of Med* 1948, June 17, v 238, No 25, 871-3, 2 figs

Two cases of typhus fever, serologically confirmed as being of the epidemic or louse-borne type, occurred in Boston in September 1946 and October 1947 The clinical features conformed to the pattern observed in Brill's disease

Both of the patients had lived in County Galway, Ireland, till they emigrated to Boston, one in 1910 at the age of 20, the other in 1913, at the age of 17 In 1903 a serious epidemic of typhus fever occurred in County Galway when the patients were 13 and 7 years of age

Complement-fixation and rickettsia-agglutination tests were carried out by Herald R Cox and J E Smadel, both of whom regarded the results as diagnostic of epidemic typhus In both cases the complement-fixation titres against epidemic antigen were two to eight times higher than those against murine antigen in the repeated tests that were carried out The epidemic titre rose to 1-2,560 in each case The results with the agglutination tests were less convincing, but when a difference in titre occurred the epidemic titre was always higher than the murine

It appeared most likely that both of the patients had suffered from Brill's disease, the form of louse-borne typhus that occurs as a recrudescence of a latent infection persisting indefinitely after an attack of louse-borne typhus

John W D Megaw

SCHMIEDER, F Das Encephalogramm nach Fleckfieber [The Encephalogram after Typhus Fever] *Klin Woch* 1948, Jan 1, v 26, Nos 1/2, 14-19, 12 figs.

The author describes the findings obtained by encephalography in 44 cases of after-effects of attacks of typhus fever which had occurred one to three years previously The paper is illustrated by 12 excellent photographs.

The patients were not selected because of the special severity of their signs and symptoms their disabilities ranged from hemiplegia with pronounced psychosis to trivial neurological manifestations.

In two-thirds of the cases, some abnormality was detected this usually consisted in enlargement or deformity of the third ventricle There was no definite correlation between the X-ray findings and the clinical features, but the author claims that the occurrence of an abnormality in the encephalogram

of a given patient increased the probability that his psychic or neurological defects had resulted from a previous attack of typhus fever. The procedure was therefore considered to be of diagnostic value.

In three cases it was found impossible to introduce air into the third ventricles, even after repeated attempts.

The author is doubtless justified in claiming that this is the first occasion on which cephalography has been employed in a systematic manner in the investigation of the persistent after-effects of typhus fever.

Jak H D Mc NE

D IGNAZIO C. Il problema del dermatifo e della lotta contro il dermatifo in Etiopia (1938-1946) [The Problem of Typhus Fever and its Control in Ethiopia (1938-1946)]. *Boll Soc Ital di Med e Igiena Trop* (Sex. Eritrea). 1947 v. 7 No. 58 423-9

In this paper it is stated that the case-fatality rate of typhus fever (house-borne) among Europeans in Ethiopia fell from 25-30 per cent. in 1937-1938 to 0-5 per cent. for the five years 1941-1946.

The causes of this astonishing fall are discussed, but even making the fullest allowance for early diagnosis, better methods of treatment and a progressive decline in the virulence of the infection, the author feels compelled to fall back on the theory that the control measures, such as improvements in hygienic conditions, louse control, and the use of vaccines, have not only increased the resisting powers of the individual but also have produced a durable attenuation of the virulence of the rickettsiae through interference with the chain of transmission and adverse biological effects on the lice.

DAVIS D E. Observations on Rats and Typhus Fever in San Antonio, Tex. *Pub Health Rep* Wash. 1948 June 11 v. 63, No. 4 743-40 figs.

The author presents information on the composition of populations of rats (*R. rattus* and *R. norvegicus*) at San Antonio, Texas, and on the presence of typhus antibodies in them.

San Antonio lies about 30 N. that is to say outside the tropics. The climate is classed as humid sub-tropical. The average rainfall is 28.9 inches and rain generally falls in every month of the year. The mean temperatures over a series of years range from 63°F. in January to 84°F. in July and August.

The paper contains information on such matters as the length of head and body of the two species classified by sex and age, the criteria for age being based on the reproductive condition, also on the sex ratio of trapped and poisoned rats. It seems that reproduction occurs throughout the year with a maximum in the period May to June.

The presence of typhus antibodies was determined by complement fixation. In adult *R. rattus* 34 per cent. were positive and in adult *R. norvegicus* 51.4 per cent. Rats from grain mills are more frequently positive than those from houses or stores and the difference is highly significant in statistical sense.

SAVOUR, S. R. VARMA, N. S. SUMAN, D. W. Typhus in Bombay. Part I. Clinical Features. *Ann R Varma & Suman*. *Indian Med J* 1948 Jan. v. 83 No. 1 (1-4) 11-15. Part II. Epidemiology. *ibid*. 1948, SUMAN & VARMA. *ibid* 5-3

During the years 1944 and 1945 more than 200 cases have been diagnosed as epidemic Calcutta typhus on the strength of Weil-Felix reactions, presumably of the Typhus OX19 type, at titres 1:100 or over.

It was possible to study 70 of these cases at hospitals in Bombay City. The average duration of the fever was 12 days, a rash was seen in 24 per cent of the cases, and the fatality rate was 2.8 per cent.

The incidence was greater in the first half of the year than in the second, there was a sudden drop in the number of cases in July and a further decline in August, flooding out of the rats by the monsoon rains was regarded as the probable cause of the low incidence during these months.

Five strains of rickettsiae were recovered from patients and another strain was recovered from one out of six rats captured in a house in which a case had occurred, a description of these strains will be given in a later paper.

No body lice were found on any of the hospital patients. The clinical and epidemiological features of the disease as described are consistent with the diagnosis of flea-borne typhus.

In an Appendix, a description is given of a new modification of the rapid slide test. The alcohol-killed suspensions of *Proteus OX19*, as supplied by the chief laboratories in India for the Weil-Felix test, are concentrated by keeping the bottles or ampoules in the ice-chest for five days and then removing the upper, relatively clear, two-thirds of the liquid with a pipette. To the remaining suspension a "small crystal" of sodium citrate and a drop of Loeffler's blue are added.

One drop of the suspension and a drop of the patient's blood are mixed on a slide which is gently rocked and a watch is kept for the occurrence of agglutination. The method was tested on 250 samples of blood whose Weil-Felix titres were known and it was found that clumping within ten seconds corresponded with titres of 1-500 or over, clumping within half a minute corresponded with a titre of 1-250, and within a minute with a titre of 1-125. When clumping was delayed beyond a minute, the result was of doubtful significance.

Fox, J P. The Long Persistence of *Rickettsia orientalis* in the Blood and Tissues of Infected Animals. *J Immunology* 1948, June, v 59, No 2, 109-14 [15 refs]

Rickettsia orientalis was recovered by mouse inoculation from the tissues of Swiss mice up to 610 days after experimental infection. Most of the mice had recovered from heavy doses of infection because of being treated with toluidine blue or methylene blue. The kidneys were the most infective organs, next came the brain and liver, the blood was less virulent because of the presence of antibodies. The urine was tested for infectivity on two occasions, with negative results.

Cotton rats were found to harbour infection in the blood and tissues up to the 102nd day after infection, the blood ceased to be infective by the 154th day, and the brain by the 269th, when the kidneys were still infective.

The author states that "the significance of these observations to the problem of the rodent reservoir in tsutsugamushi disease is obvious."

SOMAN D W & DAS MENON V K. Scrub Typhus (Mite Typhus) in Bombay with a Report on the Isolation of Canine Rickettsiae. *Indian Med. Gaz.* 1948 Jan v 83 No. 1 17 20 4 figs on 1 pl.

Weil-Felix reactions of the Proteus OXA type were observed in sera from 16 among a large number of pyrexial patients in Bombay City during the year 1948. Rickettsiae were recovered by mouse inoculation from 8 of the 12 patients investigated. The organisms were similar to *Rickettsia cynopteri* in their morphology, in the reactions produced in mice and in the effects of intra-ocular inoculation of rabbits. There was also evidence of cross-immunity against a Ceylon strain of *R. orientalis*.

In 7 of the 12 patients an eschar was observed and in 6 there was a rash.

Fourteen of the 16 cases occurred in the months September October and November.

Special attention is called to the occurrence of scrub typhus in even a metropolitan city like Bombay. [SOMAN *et al.* this *Bulletin* 1948, v 45 81.]

It has pointed out that contact with mite-infested vegetation is liable to occur in Bombay. John H. D. McGarr.

SPORZA M. Dermotifo in Eritrea. (Identificazione del virus storico murino e da zecche) Typhus Fever in Eritrea. Identification of Epidemic, Murine, and Tick-borne Strains of Rickettsiae. *Boll. Soc. Ital. di M. I. e Ig. e T. p.* (= *Eritrea*) 1947 v 7 No. 5 6 49-52.

Details are given of the isolation and investigation of two strains of rickettsiae of epidemic typhus and of one strain of the murine type, but most of the paper is devoted to a description of a number of strains of tick typhus infection.

Three tick typhus strains were isolated from patients, three from dogs collected from dogs belonging to patients, and one from the brain of a dog which harboured infected ticks. The ticks concerned were *H. p. p.* and *R. p. p.* and *R. p. p.* Two ticks of the former species obtained from an infected dog were allowed to feed on a guinea pig, which in due course yielded strain of rickettsiae.

Three strains of tick typhus rickettsiae were thoroughly studied by passage through guinea pigs and inoculation into the eye of rabbits, which thereby rise to cross immunity against the other two strains, but none immunized against epidemic or murine strains.

An outbreak of tick typhus is described in which ten persons living in a tick infested area at an altitude of 888 metres were attacked, four of the patients had inoculation eschairs. The Weil-Felix reactions were irregular, in most cases Proteus OX19 gave higher titre reactions than OXA, but in one case there was an OXA reaction of 1:320 and certain reactions with OX19 and OXA, and in one case the OXA reaction was 1:160 as compared with reactions at 1:40 with the other two organisms.

The author concludes that the tick typhus of Eritrea is more closely related to boutonneuse fever, but it comes as a shock to be told that the causative organisms are identifiable with *Rickettsia cynopteri*. John H. D. McGarr.

SPORZA M & SOLINAS V. La reazione di Weil-Felix sul siero di sangue dei cani di Asmara. Weil-Felix Reactions in the Dogs of Asmara. *Riv. S. Ital. di M. I. e Ig. e T. p.* (= *Eritrea*) 1947 v 7 No. 5 6 47-52. (In Italian summary (8 lines).)

Among 159 dogs captured at random in Asmara the following Weil-Felix titres were obtained:—

| | 1-640 | 1-320 | 1-160 | 1-80 | 1-40 | Negative |
|-----------------------------|-------|-------|-------|------|------|----------|
| Against <i>Proteus</i> OX19 | 1 | 6 | 13 | 50 | 47 | 42 |
| „ <i>Proteus</i> OX2 | 0 | 6 | 9 | 58 | 32 | 54 |

In the absence of reliable evidence the authors arbitrarily adopt a titre of 1-320 or over as evidence of the existence of rickettsial infection, this is the same standard as has been adopted for human beings

John W D Megaw

STREETEN, G E W, COHEN, R S, GUTTERIDGE, N M, WILMER, N B, BROWN, H E, SMITH, D J W & DERRICK, E H Tick Typhus in South Queensland Report of Three Cases *Med J Australia* 1948, Mar 20, v 1, No 12, 372-3

In two of the three cases described in this paper, there was a history of bite by a tick ten days or less before the onset of the fever. From the description given by the patients the tick was probably *Ixodes holocyclus*. In the third case there was no evidence of a bite but the patient had recently been walking in a "scrub area". In every case there was an eschar and lymphadenitis. The clinical features were consistent with the descriptions by ANDREW *et al* of tick typhus in North Queensland [this *Bulletin*, 1947, v 44, 202].

In one of the cases with a history of tick bite the Weil-Felix titres were *Proteus* OX19, 1-640, P OX2, 1-320, and P OXK negative. In the other case with tick bite the OX2 reaction was not tested the OX19 titre was 1-160 and the OXK reaction was negative. In the case without history of tick bite the OX19 titre was 1-320, the OX2 and OXK titre was 1-40.

The authors think it likely that in the past a number of cases of tick typhus have been regarded as murine typhus because of a positive reaction against *Proteus* OX19

PAYZIN, S & GOLEM S B Türkiye de Q humması (Rapor I) [The Presence of Q Fever in Turkey] *Türk İhtiyat ve Tecrübe Bilyoloji Dergisi* Ankara 1948 v 8, No 1, 94-113, 8 figs on 4 pls [12 refs] English summary p 116

The authors inoculated 24 guinea-pigs intraperitoneally with blood from 16 patients who had clinical atypical pneumonia. 7 of the animals developed pyrexia and were killed and examined post-mortem, their spleens were enlarged and *Rickettsia burneti* was recovered from them.

Complement fixation tests with Q fever antigen obtained from the Rocky Mountain Laboratory, were performed on 100 specimens of serum from patients having atypical pneumonia. 24 of these were positive at titres of 1/10 to 1/320.

Positive results were also obtained, however, in 13 of 115 sera sent for the Wassermann reaction (including 4 which also gave a positive W.R.), but the titre only exceeded 1/40 in one case.

Sixty specimens of serum from domestic animals were examined by the complement fixation test and 13 were positive.

The authors are pursuing the question of a possible relation between Q fever and contagious pleuro-pneumonia in goats.

ROSOVY L. WEST H. E. & BOWEN A. G. Q Fever: Case treated with
Streptomycin. J. Intern. Med. 1948, June v. 28 No. 6 1187-92.
3 figs. 14 r (a)

Q fever has recently been identified in the Artesia area of Los Angeles
County. A case of Q fever is reported here with clinical and roentgenographic
findings consistent with this diagnosis and confirmed by positive complement
fixation tests. Treatment with streptomycin was instituted and proved
satisfactory although further clinical investigation is necessary to establish its
efficacy in this disease.

BLANC G. BRUNEAU J. PORTHOT R. & DELAGE B. Quelques données sur
la Q fever (maladie de Derrick Burnet) expérimentale. (Some Findings
in Experimental Q Fever) Bull. Acad. Nat. M. d. 1948 v. 132, Nos. 13-14
243-50 4 figs.

The authors describe the results of a considerable number of experiments,
carried out primarily as a therapeutic measure in which patients (presumably
suffering from mental disease) were inoculated with the rickettsiae of Q fever.

Three strains of rickettsiae were used: two of these were from ticks found
infected in Morocco and the U.S.A. the third was isolated from a patient in
Athens. A significant difference was observed between the three strains.
The routes of inoculation were intramuscular, intradermal and conjunctival.
Some of the infecting suspensions were obtained from the spleens of guinea-pigs,
others from ticks (*Rhipicephalus* or *Hyalomma* sp.).

Inoculation by the intramuscular route with spleen substance caused a short
spell of fever lasting three to five days, with an incubation period of one or
two days: the general symptoms were negligible but the local reaction was
pronounced. Rickettsiae could be isolated from the patients' blood.

Tick suspensions inoculated by the same route caused more prolonged fever,
often of a two-phase type, but the general symptoms were trivial.

Intradermal injections of spleen substance were employed in ten cases: the
only general reaction observed was slight fever in two; the local reaction
lasted about ten days and exceptionally there was an eschar. Rickettsiae
could be isolated from the blood in only one of the cases.

Instillation by the nasal route with a few drops of tick suspension was
employed in six cases: the only result was a slight rise in temperature.

The only cases in which characteristic pulmonary signs occurred were two
in which the patients were caused to inhale heavily infected vapours
administered by the aerosol apparatus and a mask: the two operators (though
protected by masks) and two other persons who had been present in the vicinity
of several yards, also became infected and developed pulmonary manifestations.

Even the symptomless attacks caused by intradermal inoculation produced
a state of immunity.

Rickettsiae-agglutination reactions at titres of 1:5 to 1:50 were observed
in all the 22 cases in which tests were carried out. (Journ. B. D. M. Soc.)

BIEBIGER R. & OLLERMAN L. Experimentelle Untersuchungen über die
Infektion mit *Rickettsia quintana* (pudovik). Experimental Investigation
of Infection with *Rickettsia quintana* (J. m.). Ztschr. f. Bakt. 1947
Jan. 6. 127 No. 1. 41-8.

The authors found that suspensions of the organism in a *Arctobacter*
quintana caused the typical intracellular action in albino mice, and that

homologous immune serum prevented the reaction, whereas anti-typhus serum had no inhibiting effect

The homologous immune serum did not kill the rickettsiae, these remained infective to lice after its application

The serum of human convalescents from trench fever also inhibited the *R. quintana* intracutaneous reaction, this observation forms the basis on which a practical test for trench fever can be developed. The serum of persons immunized by trench-fever vaccine had no pronounced inhibiting effect on the reaction

John W D McGaw

BIELING, R & OELRICHS, Lilly Beobachtungen über die Dauer der Infektion mit *Rickettsia quintana* (pediculi) [Observations on the Duration of Infection with *Rickettsia quintana* (pediculi)] *Ztschr f Hyg u Infektionskr* 1947, Jan 6, v 127, Nos 1/2, 49-53

The authors mention that the American Trench Fever Commission appointed during the first world war found that the blood of trench-fever patients might remain infective up to 442 days after the onset of the attack

The present observations were made on Russian prisoners of war employed as "donors" of blood to clean laboratory-bred lice which on several occasions became infected with *Rickettsia quintana* although the prisoners had not been exposed to any risk of infection for two or three years, it was assumed that infection might possibly exist for much longer periods. The infectivity was not associated with recrudescences of the disease in recognizable form, in some cases there were single spells of fever in others there were two or more spells at long intervals, and after these trivial illnesses infectivity to lice might persist for several weeks

John W D McGaw

BARTONELLOSIS

RICKETTS, W E Intercurrent Infections of Carrion's Disease observed in Peru *Am J Trop Med* 1948, May, v 28, No 3, 437-51, 6 figs [33 refs]

[A paper of great interest and one to stimulate observation, for the findings are very definite though the number of cases on which they are based is comparatively small.]

Out of 105 cases of Carrion's disease, 50 were attacked by intercurrent infections. Malaria heads the list, as is only natural since the two diseases are endemic in the district where the investigation was carried out. The course of the bartonellosis did not seem to be affected by the malaria though the clinical features of both diseases might be modified. The sweating, splenomegaly and monocytosis present are due to the malaria. When the latter infection occurred in the pre-eruptive stage its course might be very atypical, the characteristic chills and fever might be absent.

Intestinal infections—including under this heading infections at first systemic, such as enteric fever and others of the group—were most serious. Of four patients with a complicating typhoid fever three died, as did both of two with *Salmonella paratyphi B* infection, three others had what the author calls an "anaerobic intestinal septicæmia", the organism not being identified, and all died. *Entamoeba histolytica* infection is another dangerous complication. The author saw three such and all ended fatally after an acute illness with high fever and symptoms generally like those of the *Salmonella* infection, and at autopsy multiple necrotic septic foci were found in the liver and spleen.

Sciurus nigrum was found to circulate virus after inoculation with the Azibi and the J Z strains, but not with the O C strain. However, antibodies were developed against all three strains.

The large *Cuniculus paca* was the only species tested which invariably showed circulating virus after inoculation and developed neutralizing antibodies. These last two species also showed most virus in the blood stream, but the amount circulating was far below that appearing in certain infected primates.

Eight species were also tested against the French neurotropic strain but only one, *Nectomys squamipes* was found to be susceptible. E Huddle

DENGUE AND ALLIED FEVERS

MELNICK, J. L. & PAUL, J. R. Experimental Fort Bragg Fever (Pretibial Fever) in Chimpanzees. *Proc Soc Exper Biol & Med* 1948, Mar, v 67, No 3 263-8, 1 fig.

This paper deals with a study of the filtrable virus of the short fever described by DANIELS and GRENNAN and called by them pretibial fever because of the frequent occurrence of a rash on the shins [see this *Bulletin*, 1944, v 41, 278]. An exhaustive investigation by a team of experts failed to disclose the agent.

The virus was later isolated from a patient by TATLOCK, from whose description (*J Clin Investigation* 1947, v 26, 287) the authors quote in stating that it is lethal to hamsters and causes fever in guinea-pigs and rabbits. Tatlock is also quoted as stating that the strain was maintained through 23 serial passages in embryonated eggs and then successfully inoculated into 14 human volunteers, most of whom developed a short spell of fever lasting one or two days, and in "some" of whom there was a pretibial rash.

In the present study the strain of virus employed was received from Tatlock, it was maintained by transmission through hamsters and was found liable to deterioration even when stored at a temperature of -70°C .

Brain suspensions from infected hamsters, when inoculated into a chimpanzee by combined intracutaneous, subcutaneous, and intramuscular routes, caused a characteristic attack of pretibial fever, the incubation period was 10 days, the fever lasted about two days, there was a raised erythematous patch on the right shin and another on the left forearm, blood taken during the spell of fever and inoculated by the same routes into another chimpanzee gave rise to the formation of neutralizing antibodies, but the animal was refractory and its temperature could not be taken. The first chimpanzee also developed neutralizing antibodies and was found immune when challenged with a further dose of the virus.

Two other chimpanzees developed short febrile attacks after inoculation, and from one of them the virus was transmitted to hamsters by blood inoculation, in both of them, and also in a fifth chimpanzee, whose temperature could not be taken, the presence of antibodies was demonstrated.

Large numbers of hamsters were used for testing the activity of the virus and for the detection of neutralizing antibodies.

Four rhesus monkeys were inoculated with suspensions which were lethal to hamsters but the results were entirely negative.

PLAGUE

MEYER, H. F. & FOSTER, L. E. Measurement of Protective Serum Antibodies in Human Volunteers Inoculated with Plague Prophylactics. Reprinted from *Stanford Med. Bull.* 1948 Feb. v 6 No. 1 75-9

It is not sufficient to establish the bare fact of efficient immunization and the need remains in many infective diseases to determine its degree and duration. Agglutination tests, complement fixation tests and whole blood tests have all proved inadequate. A test known as the mouse protection test is in use now for the measurement of degree of passive immunity in yellow fever typhoid fever and dysentery. The authors apply this to the case of plague and use a subcutaneous infective challenge dose of 1,000 *P. pestis* organisms in 0.2 ml. broth equal to 100 MLD. The test mice were of uniformly susceptible ABC inbred strain and each received 0.5 ml. undiluted immune serum from human volunteers intravenously. The volunteers were separated into 4 groups of 10 each, according to the nature of their prophylactic inoculation. — I. Army prophylactic 3 injections 7 billion formalin-killed. II. Fraction I antigen 2.5 mgm. in 3 doses. III. One injection of 1,000 million avirulent No. 1122. and IV. One injection of 1,000 million avirulent Tjilexle. As the differences, first in percentages of mortality and second in the length of survival time are not strikingly significant when considered separately, but when the two factors are considered together the results of the test become significant, the authors unite the two factors in a protection index, the percentage mortality divided by the average time of death.

Conclusions drawn are briefly. — I. Administration of purified Fraction I plague antigen (this *Bullet.* 1947 v 44 717) to non-immune human volunteers results in the production of large quantities of protective antibodies in the blood. Formalin killed virulent plague bacilli and one strain (No. 1122) of living avirulent bacilli are decidedly less effective. The well known strain Tjilexle as used in these studies proved non-immunogenic. — Adequate protection requires reinoculation and this stimulates a higher level of antibodies than the primary inoculation, but some individuals fail to react to these "booster" antigenic doses.

CHOLERA

TREK, Ilse. Die Cholera in der Schweiz. Cholera in Switzerland. *Zuch. f. Hyg.* / *Monatschr.* 1947 Jan. 6. 127 No. 1 2 169 81 5 cols. 1 p. is a historical review

RAO, S. R. Role of *Palkis* (Moving Religious Fairs) in the Epidemiology of Cholera with special reference to Sri Eknath Maharaj *Palki*. *India M. J. Gaz.* 1947 Dec. v 82, No. 12. 46-50

Pilgrimages and shrines in India and Arabia have been epidemiologically associated with cholera outbreaks. In the case of the present pilgrimages along a route of over 300 miles traversed on foot, we have an instance of miniature pilgrimage during which a cholera epidemic might have taken place. It is a common custom for palanquin or *palki* carrying the sandals of a saint to be the centre of the procession. Pilgrims start with the *palki* and obtain fresh accoutrements en route. In the same way pilgrims disperse

or arrive back on the return journey Cholera cases may be occurring at the commencement of the journey, may be present in villages on the way, and may be brought back again from the shrine of attendance This pilgrimage started in 1941 "from Patan a town heavily infected with cholera" and came under the author's control only with its arrival within the dominions of the Nizam of Hyderabad He had it under supervision both going and coming within the State and it swelled at one time to as many as 1,500 persons An occasional case of cholera required attention on the outward journey, but in none of the cases did it spread, while on the return of the palki, with nearly 1,100 pilgrims, not a case occurred The precautions adopted were compulsory (indirect) inoculation of all pilgrims, treatment of wells with permanganate or bleaching powder, and great care over the feeding of the pilgrims, which was the obligation of villagers *en route* Inoculation is called compulsory and indirect because no pilgrim was allowed to join who had not been vaccinated It is reasonable to claim that these precautions prevented the outbreak of cholera among the pilgrims themselves and among uninfected villages, through which they passed or to which they gave off their fellow pilgrims

GOHAR, M A, ELYAN, A, MAKKAWI, M, EISSA, A & BASHATLY, A The Viability of Pathogenic Intestinal Organisms in Sea Water with special reference to *Vibrio cholerae* *J Roy Egyptian Med Ass* 1948, Apr, v 31, No 4, 358-72, 3 maps

It seems certain that all coastal sea water into which local sewage is discharged will be in greater or less degree diluted sewage The viability of an organism like that which is designated the "true" cholera vibrio is important Earlier work, done at a time when selection had not established the definition of the cholera vibrio in its narrowest sense, gives little help in solution of the problem The authors have contributed direct data relating to the recent cholera epidemic in Egypt Samples of water from several Egyptian ports with beach lines on the Mediterranean, the Nile, at the entrance of the Suez Canal and at Suez were artificially contaminated with 5,000 million cholera vibrios per litre and kept at a temperature of about 18°C with the intention of testing them daily for viable cholera organisms The cholera vibrio, however disappeared from all the samples in about 24 hours this could be interpreted as due to the overgrowth of harder organisms or to the presence of an antibacterial substance in sea water The next step was to try the samples out after getting rid of other organisms first by sterilizing, by adjustment of pH, and by making up a synthetic sample of sea water The result of this trial showed that "the life of the organism is very short only in the filtered water which probably contains an anti bacterial agent and is much longer in the autoclaved samples" Filtration was through Sartz filters and autoclaving probably destroyed not only existent organisms but also the hypothetical antibacterial substance Viability of the cholera vibrio was especially long after adjustment of pH to suit its requirements Other experiments were carried out for organisms other than the cholera vibrio and are pertinent to the disposal of sewage generally by discharge into coastal sea water The remarks towards the end of the article sum up the position further — 'From the point of view of bathing and frequenting seaside resorts the danger of discharging sewage into the sea is overestimated The main risk of infection with pathogenic intestinal organisms in the sewage seems to lie not so much in the contamination of the water itself as in the contamination of shell fish' Aesthetic reasons may of course, be an important consideration in a coastal area for the imposition of regulations relating to the discharge of sewage

BURROWS, W. & HAYES, Isabelle. Studies on Immunity to Asiatic Cholera. V The Absorption of Immune Globulin from the Bowel and its Excretion in the Urine and Faeces of Experimental Animals and Human Volunteers. *J Infect. Dis.* 1948, May-June, v. 82, No. 3 231-50 12 figs. [16 refs.]

A preceding study IV has already been abstracted [this *Bulletin* 1948 v. 45 335] and indicated that immune coproglobulin indistinguishable from immune serum globulin was present in the faeces of previously immunized guinea-pigs that had received experimental enteric infection with the cholera vibrio. The present study continues the research into the origin of the faecal antibody—whether it might be derived from seepage of serum antibody or direct from antibody-forming cells of the lymph follicles of the intestine; the permeability of the intestine to a large globulin molecule; and the behaviour of homologous and heterologous globulin in the passively immunized animal. The conclusions to the detailed experimentation are shortly—1 Immune globulin immunologically indistinguishable from serum globulin is excreted in the faeces and urine of actively immunized guinea-pigs and human volunteers. It is independent of serum antibody and therefore is not derived from it. 2 Serum globulin is excreted normally in urine and faeces and immune globulin of immunized guinea-pigs is a partial substitution for normal globulin in the excreta. 3 Antibody appears in the faeces and urine of guinea-pigs passively immunized with homologous or heterologous antiserum. 4 Homologous and heterologous immune globulin administered to the guinea-pigs by intragastric inoculation is absorbed in large amount directly from the bowel without modification of its immunological properties and it is evident that the immune globulin can readily pass in either direction through the bowel wall.

W. F. Harvey

SAFWAY, V. & ADHAM, I. Fluid Balance in Cholera. *J Roy Egyptian Med Ass.* 1948, Apr. v. 31 No. 4 300-303.

Depletion of water and depletion of salt cause the most serious symptoms in cholera. Dehydration requires urgent and immediate treatment but this treatment should be followed by a careful analysis as to how far the alteration in fluid balance is due to pure water depletion or pure salt depletion respectively. "Cholera presents a combination of the picture of both pure water and pure salt depletion. As a result of pure water loss, tissue fluid and blood plasma become hypertonic and water is withdrawn from cells. With salt depletion the reverse takes place and tissue fluid becomes hypertonic. As the kidneys excrete water in an endeavour to decrease the tonicity of tissue fluid, the volume of tissue fluid then is set against the volume of urinary volume marked reduction in blood volume due to dehydration but in the later cases

intravenous saline, till the specific gravity dropped to 1060, after which it was sufficient to make the patient drink plenty of fluid. As there is usually reduction in the alkali reserve and tendency to acidosis, intravenous 4 per cent sodium bicarbonate is recommended. The work of MARRIOT [this *Bulletin*, 1948, v 45, 208] has greatly clarified the symptomatology of cholera. W F Harvey

SAFWAT, Y & ADHAM, I **Uraemia in Cholera** *J Roy Egyptian Med Ass* 1948, Apr, v 31, No 4, 309-21

A reference is made to the findings of CHATTERJEE and SARKAR [this *Bulletin*, 1941, v 38, 583] which are summarized and which had led those authors to conclude that uraemia in cholera was not due to any structural change in the kidney, but that the cause was extra-renal and pre-renal. Safwat and Adham's own observations tend to confirm this view, and briefly are —(1) Initially all cases had albuminuria which disappeared with recovery of renal excretory function and drop in blood urea, oliguria changed to polyuria, even though blood urea was still high, the specific gravity of the urine was low, and began to rise only when blood urea became normal, casts were sometimes found and a low urinary chloride increased with improvement of the case and with drop in blood urea. (2) Blood uric acid, blood creatinine and blood urea clearance were highly correlated with blood urea values, positively, or negatively. Little evidence was found, from estimation of blood chlorides, of hypochloreaemia. All the results pointed to a marked acidosis initially and gradual attainment of normality with general improvement and with treatment. Clinically the symptoms in cholera were those of dehydration, and symptoms of uraemia were slight even with very high blood urea.

"In other words there was a picture of renal failure developing acutely, coming to a maximum and finally, in the majority of cases, resolving completely in a short time."

Structural changes in the kidney having been excluded as a cause for pre-renal azotaemia there remained the question of the mechanism of the impairment of renal function. Four factors are considered —hypochloreaemia, low blood pressure, disturbance of acid-base balance and nephritis due to toxæmia. The first and last of these explanations are rejected and leave the remaining factors as the explanation of symptoms and high blood urea in cholera. W F Harvey

AWNAY, A **Some Haematological Aspects of Cholera Infection** *J Roy Egyptian Med Ass* 1948, Apr, v 31, No 4, 351-7

The author, in Cairo, studied the following haematological aspects of cholera (1) the degree of haemoconcentration, (2) the leucocytic reaction, (3) the erythrocyte sedimentation rate, (4) the erythrocyte fragility.

The degree of haemoconcentration varied widely the specific gravity of the blood was between 1056 and 1078 and the volume of packed red cells was from 48 to 80 per cent, haemoglobin varied from 85 to 135 per cent and the highest figure for red cells was 7,500,000 per cmm. The author found that in almost every case these four data gave a fairly reasonable indication of the degree of haemoconcentration and correlated closely with clinical findings but they had no prognostic significance. The constitution of the plasma also reflected the dehydration in 18 of 25 cases the plasma specific gravity was above 1030 and in 21 of 25 the plasma protein concentration was 8 gm per cent or more.

Leucocytosis of 20,000 to 30,000 per cmm was quite common, and this increase could not be explained solely on the basis of haemoconcentration.

The polymorphonuclear leucocytes were mainly involved and they also showed some left shift. The total leucocyte counts remained high (average about 12,000 per mm³) after the acute stage was over and the dehydration had been corrected and even during convalescence. At this last stage eosinophiles characteristically increased and the author suggests that this point should be investigated further.

The erythrocyte sedimentation rate was estimated in 13 cases before and in 11 after rehydration treatment. The Wintrobe technique was used and corrected by haematocrit readings. Before treatment the corrected E.S.R. range was 0.45 to 1.7 mm. minute (average 0.7 mm.) and after complete rehydration it was 0.6 to 1.5 mm. minute (average 1.0 mm.). The normal reading is 0.1 to 0.3 mm. minute by this method. It is suggested that the higher viscosity of the blood before rehydration interfered with the sedimentation rate. The corrected E.S.R. range in 9 patients during convalescence was 0.3 mm. minute to 0.6 mm. minute (average 0.45 mm.).

The finding of an increased E.S.R. during the acute stage of cholera and for some time afterwards differs from that of the Indian workers (not specified) and the discrepancy is attributed by the author to his having corrected the results by haematocrit readings which he regards as essential.

Increased erythrocyte fragility during the acute stage of the disease was found in 13 of 14 patients when the Sanford technique (diminution, dilutions of NaCl solution) was used and in 6 patients tested by the Wyman method (increasing dilutions of serum with distilled water). In the latter 6 patients, the icterus index was also high (12 to 23 units) in the acute stage but fell to less than 8 units during convalescence. The author discusses the causes of the increased fragility. He believes and quotes experimental evidence to support his belief that in addition to the cholera toxin itself deficient capillary circulation tends to increase red cell fragility, probably trauma of the cells in marked dehydration and increased blood viscosity may also contribute to the fragility. He suggests that the icterus index is increased as a result of increased phagocytosis of the fragile erythrocytes by reticulo-endothelial cells, this would be favoured by stagnation of blood because of deficient and slow circulation.

EL. RAWI, A. H. Clinical Study of 689 Cases of Cholera Isolated in the Abbassa Fever Hospital. *J. Roy. Egyptian Med. Soc.* 1948, 32, 31-44.
322-50.

It must have been a trying experience for a medical man with no previous experience of cholera to take charge of a large and sudden serious epidemic even though it also made sudden disappearance. Excellent details are given of this experience which present a vivid picture of the boiler patient. Diarrhoea, vomiting and dehydration effects make up the symptoms. The diarrhoea is painless and the vomiting is unaccompanied by nausea. One has always been accustomed to associate colourless rice water stools with cholera and it is interesting to note that the colour is first faecal becomes colourless and then with the improvement of diarrhoea the stool becomes coloured semisolid and solid as bile returns. Degree of dehydration as measured by the copper plate method for specific gravity of whole blood which ranged from 1.050 to 1.078 in different cases. Blood pressure might be so low that it could not be taken at all or else very low (70 or less) systolic pressure and no measurable diastolic pressure was found. Fever was seldom present and infrequent symptoms were lumbago, headache, anuria, and abdominal pain. It was found that the concentration of blood urea, an early feature in cholera, is not related at all to the haemococoncentration.

Similarly there was seldom any correlation between "blood chlorides and blood urea in the sense that as the blood urea decreased, the chlorides increased". Of complications, high blood urea concentration was the most common. In fact "it should be considered as a symptom and not as a complication" of cholera. Only a minority of these cases showed uraemia and that carried a grave prognosis.

The carrier and contact questions are answered in the data that 50, 91.7 and 100 per cent of carriers were free of vibrios after the first 5, 10 and 15 days respectively. Contacts numbered 2,035 and the number of healthy carriers among them was 84, none of whom showed any signs of gastro-intestinal illness. Cholera rarely developed among contacts. Pathological findings in necropsies and histology are described and finally treatment is critically considered. —Treatment should be started as early as possible and it must be recognized that "the immediate danger to life is due to dehydration and circulatory failure". It is quite sufficient to give fluids by the mouth in patients with blood specific gravities up to 1060, and 400 ml of normal salt solution should be given intravenously for each degree above that figure, firstly at 2-5 litres an hour and then at a slower rate. Acidosis was combated with "the addition of 40 gm sodium bicarbonate to every litre of normal sodium chloride solution", which was passed through a Seitz filter. Digitalis was the heart stimulant used and sulphonamide drugs produced no effect on the course of the illness or on the case mortality.

W F Harris,

carried out on a hospital population, thus restricting it to incidence and fatality in previously vaccinated and non-vaccinated patients. Total admissions to hospital were 430 patients. Out of 281 non vaccinated patients 69 died, while out of 149 vaccinated 14 died—a result in favour of the vaccinated. Other data relate to the decrease in incidence and death rate with the lapse of time following inoculation and to the relative value of a single or a double dose of vaccine. Fatality rate was 9.81 per cent in patients vaccinated with a single dose 8.10 with a double dose and 4.53 per cent in the non-vaccinated. The current question was taken up to determine the duration of excretion of vibrios in contact-carriers and healthy contact carriers with the finding of a maximum period in the former of 33 days and in the latter of 15 days. One of the conclusions drawn is that vaccination not only afforded "a definite degree of protection but also lowers the fatality rate."

AMOEBIASIS AND INTESTINAL PROTOZOAL INFECTIONS

FULLER E. C. LEWIS Ruth, HEILBRUN Ilse HICKMAN Mary L. M. & EVERITT Martha G. Posibles determinantes de la patogenicidad de la *Entamoeba histolytica*. I. Estudio de sus asociaciones bacterianas y su susceptibilidad a los antibióticos. [Influences determining the Pathogenicity of *Entamoeba histolytica*. I. Study of the Bacterial Associations and their Susceptibility to Antibiotics. *Medicina Mexico* 1948 May, 5, v. 28 No. 558, 206-10.]

[This is a translation of a paper delivered at a Medical Congress in Mexico. It deals with a subject of the highest importance. That the growth of *E. histolytica* is influenced by associated organisms is well known and the varied effects of the infection in man may be due to the nature of these organisms. The authors have investigated the bacteria associated with 11 strains of the amoeba, 18 already known, isolated or recorded by Fullin and their fresh strains. In 12 cases the species of bacterium present has been determined; they were mostly Gram-positive cocci and Gram-negative non-pathogenic bacteria of the coliform type. By means of antibiotics penicillin and streptomycin and by sulphadiazine in amounts insufficient to harm the amoeba the organisms were removed from the growths. The resistance of the bacteria varied greatly: some yielded readily, some needed relatively strong concentrations, some were quite unaffected. It was observed that the trophozoites might resist the action of high concentrations of penicillin and streptomycin for several hours and later develop well in the tubes containing an organism designated T. The early sterility and later development are attributed to late growth of spore-forming bacilli, inhibited in the early stage, or secondly to the presence of the antibiotic until diluted sufficiently in the course of peritoneal resorption, or thirdly to faulty technique. The first is thought the most probable.]

Tests are to be carried out on susceptible animals with the amoeba and with known isolated bacteria. [The paper contains a table of references made to several tables (numbered) which have not been included in the present text.]

H. Harold Scott

withstand a concentration of 1/1,000 Soludagenan [α (*p*-aminobenzenesulphamido) pyridine] but that the latter behaves in a different manner. The following observations were made in the case of *E. invadens* —

(1) With concentrations of 1/100 to 1/500 there was no growth in the tubes
(2) In concentrations of 1/600 to 1/2,000, cysts formed from the inoculum, but no trophozoites. Subcultures were negative

(3) In concentrations of 1/2,500 to 1/8,000 some trophozoites and fairly numerous cysts were present after 5 days, but the vegetative forms were not seen after the 10th day, cysts only being present by then. Subcultures were negative

(4) In a concentration of 1/10,000 there were numerous trophozoites and cysts after both 5 and 10 days, but subcultures into a medium containing 1/10,000 of the drug were negative

(5) Below this concentration, both cultures and subcultures were unaffected. Soludagenan therefore exerts a specific action on *E. invadens*, and is the first sulphonamide shown to be an amoebicide. The authors think it probable that other sulphonamides may be found to exert a specific action on *E. histolytica*, in which case their value in treatment would be enhanced as they also act on the accompanying bacterial infection. EL GHAFAR, Y A. Atebrine in Amoebic Dysentery. *J Roy Egyptian Med Ass* 1948, May, v 31, No 5, 456-60

Twenty patients harbouring vegetative *Entamoeba histolytica* in the stools were treated with atebirin (mepacrine) in varying dosage. Symptoms lessened in a few days and had usually vanished in a week. No parasites (48-hour stool examinations) were seen during, or for 2 weeks after, treatment, except in one case where a few cysts were found. Concurrent infections with *Giardia intestinalis* and *Trichomonas hominis* disappeared with the larger doses of the drug. *Ascaris* ova did not do so. A R D Adams

DURIEUX, C, TRENOUS, J, TANGUY, F, ROBIN, C, RAOULT, A. Recherches sur les propriétés thérapeutiques de la conessine. I. Essais préliminaires dans le traitement du paludisme et de l'ambiase intestinale. L'émétine sera-t-elle détronée par la conessine [DURIEUX, TRENOUS & TANGUY] *Méd Trop* Marseilles 1948, Jan-Feb, v 8, No 1, 7-11. II. Nouveaux essais de traitement de la dysenterie amibienne par le chlorhydrate de conessine [TANGUY, ROBIN & RAOULT] [Studies on the Use of Conessine in the Treatment of Malaria and Amoebic Dysentery] *Ibid* 12-31, 2 coloured graphs

I. In 1935 a study was instituted into the African pharmacopoeia, and of the plants used locally in French West Africa for therapeutic purposes. Among these were specimens of a root, known as "seoulou" and identified as that of *Holarrhena africana*, which is employed for its diuretic and anti-blennorrhagic properties. Analysis showed its composition to be identical with that of Kurchi, *H. antidysenterica* long used in India as an antidysenteric, the active principle of this is conessine, which constitutes about 60 per cent of the total alkaloidal content. *Séoulou* appears to be identical with the "kumbanzo" of Mozambique, which was referred to as a febrifuge by Livingstone in 1856. During the quinine shortage in French W Africa during 1940, the alkaloids of *H. africana* were extracted for investigation of their antimalarial properties. Iodobismuthates of the total alkaloids were not tolerated by the oral route, but on intramuscular

KLATSKIN G & FRIEDMAN H. Emetine Toxicity in Man: Studies on the Nature of Early Toxic Manifestations, their relation to the Dose Level and their Significance in determining Safe Dosage. *Ann Intern. Med.* 1948 May v 28 No. 3 892-915 2 figs. [57 refs.]

Emetine is necessary in the treatment of amoebiasis but fear of toxicity has led to its employment in ineffective dosage. With reasonable care moderate to large doses may safely be given. The early minor manifestations of emetine poisoning in man have received inadequate attention. The authors have re-studied these in 93 patients in a U.S. Army hospital. All the patients were confined to bed under close observation during the intoxication. Particular attention was paid to the blood pressure and the pulse rate and electrocardiogram readings were taken before and during treatment at intervals of three days. The amounts of emetine given ranged from 1 to 27 grains and the drug was given hypodermically intramuscularly or intravenously.

In 91 per cent. of the 93 patients there was some evidence of emetine toxicity. The symptoms encountered fell into four categories: local, gastro-intestinal, cardiovascular and neuro-muscular. The side-effects were multiple in 70 per cent. of the patients; in 21 per cent. they were limited to one system. The local reaction to the drug was one of the most troublesome; it may be less if the injection is subcutaneous rather than intramuscular. Intravenously emetine did not prove more toxic though transient immediate reactions were more frequent. The theoretical objections to intravenous medication are based on the sudden deaths due to ventricular fibrillation which have been seen in experimental animals. Such accidents have not been reported in man but are potential hazards which render routine intravenous therapy unwarrantable. Generalized weakness, electrocardiographic changes and diarrhoea occurred in about half the patients. Signs and symptoms of toxicity in some cases made their appearance after the first dose of emetine but in most they were not manifest until the 10th day of treatment. In a surprisingly high proportion of cases the signs were transient in spite of continued drug administration; their severity was usually mild or moderate with little tendency to increase and they rarely continued more than a week after cessation of treatment.

Indications for stopping the drug were precordial pain (in three patients), persistent electrocardiographic changes (in two), neuritis (in four), fainting (in one), nausea and vomiting (in one) and quivering of the muscles and weakness (in one patient).

"Emetine neuritis" was studied, and, in common with similar cases reported in the literature it seemed attributable primarily to a disorder of the muscles rather than to a disturbance of the nervous system. The usual signs of neuritis such as loss of reflexes, changes in sensation and muscular atrophy are usually absent in emetine neuritis and the condition is considered to be a toxic myositis rather than a neuritis.

During the quinine shortage in French W Africa during 1940, the alkaloids of *H. africana* were extracted for investigation of their antimalarial properties. Iodobismuthates of the total alkaloids were not tolerated by the oral route, but on intramuscular

Infection in doses of 0.2 gm. daily into 7 persons suffering from primary benign tertian malaria they were not found to control their infections.

After a study of the literature on kurchi, a dozen cases of acute or of chronic intestinal amoebiasis were treated during 1941-2 with the hydrochloride of conessine the salts of the secondary alkaloids having been found to cause intolerance when given by the mouth were eventually discarded. The results of oral and of subcutaneous injection having been found similar the drug was usually given in cachets by the mouth in doses up to 0.3 to 0.4 gm. daily to a total of 2.4 gm. over a period of 8 to 9 days. In every case so treated the clinical symptoms rapidly subsided and the stools became normal. One patient relapsed 2 weeks after 0.75 gm. of conessine hydrochloride subcutaneously and 1 gm. of the total alkaloids by mouth retreatment with 0.2 gm. conessine hydrochloride daily for 8 days resulted in [clinical] cure. Another case of chronic amoebiasis previously unsuccessfully treated with emetine acetyltartrate, and other drugs was clinically cured within a week by doses of 0.1 gm. thrice daily. In a third case of double infection with amoebae and with trichomonads both parasites disappeared after a similar course of treatment. Conditions at the time prevented adequate follow-up of the cases to determine if parasitic cure had been obtained, and the investigation had to be abandoned until 1947.

II. Between April and September 1947 6 Europeans and 6 Africans suffering from amoebiasis were treated with conessine hydrochloride the clinical effects, the dosage, the therapeutic action, the side effects and the excretion of the drug in these cases were studied in detail. The initial dosage adopted is at least 0.5 gm. daily by the mouth for an adult (roughly 0.01 gm. per kilo of body weight over 5 to 6 days) this is decreased during the last day of treatment and the gross dosage adopted is 3 to 5.5 gm. There was immediate relief from pain and the disappearance of tenesmus within 48 hours in the acute cases, and the physical signs disappeared, the stools becoming formed and normal in appearance in all of them. In 7 of the 12 cases treated parasites completely disappeared in the others amoebae and cysts persisted. *Trichomonas* infections were cured in a few days. Salivation occurred in two of the European patients. Insomnia appeared early and increased in intensity during treatment it was associated with disturbing dreams and in some cases with disorientation of time and place. Most patients developed fine tremors which became marked and persisted for some days after the completion of treatment. Vertigo and tinnitus occurred in about half the cases.

Conessine caused none of the changes in the urine associated with irritation of or damage to the renal epithelium. It produced a slight but inconsistent diuresis. The urinary excretion of the drug is slow its diuretic action and its excretion through the kidneys are depicted in two graphs.

Conessine compares favourably with emetine in the control of acute amoebic dysentery and can be safely given if the nervous and psychic manifestations attending its use are controlled by the use of one of the barbiturates.

BROWN, E H *Giardia Lamblia* The Incidence and Results of Infestation of Children in Residential Nurseries *Arch Dis in Childhood* 1948, June, v 23, No 114, 119-28

The nursery in which this investigation was carried out is one of the largest and most modern in London. The incidence of *Giardia* infestation on admission in children from one to three years was 26.6 per cent and there was no significant difference in the incidence between the age groups.

Direct examination of the stools for *Giardia* cysts is unreliable, and unless repeated examinations are made, a large number will be missed. The ether concentration method consists of the emulsification of a portion of faeces the size of a large pea in normal saline in 1 oz screw-cap bottle, a layer of ether is added and the bottle is then shaken. The lower layer of saline containing cysts and ova is pipetted into a centrifuge tube and spun at 1,500/min for 5-7 minutes. The supernatant fluid is discarded and a loopful of the deposit is placed on a slide with Gram's iodine.

In a group of 86, the incidence in thirty who had previously attended a day or residential nursery was 50 per cent, but that in 56 who had not done so was only 14.3 per cent.

The great majority of the long-stay children over one year old were infested, in one random group the incidence reached 79 per cent, but under the age of one year the incidence was low. There was a rapid rate of infestation after admission. On the other hand the incidence in adults was 3.7 per cent on one examination. There was no significant difference in height and weight between children who had *Giardia* cysts in the stools and those who had not. On admission there was no significant difference between the stools of a *Giardia*-infested child and those of a child not infested.

The inference is that some factors other than *Giardia* must play a part in accounting for the difference between children on admission and those long resident, but no significant difference was found in the haemoglobin levels. There was no evidence of any marked inability on the part of the *Giardia*-infested children to absorb fats.

The group of *Giardia*-infested children treated with mepacrine showed a significantly greater rate of weight gain than the control group and there was a marked decrease in the incidence of loose stools.

The improvement following mepacrine was a gradual process which might be expected to occur in a chronically inflamed intestine, but there appeared to be no definite relationship between the occurrence of *Giardia* infestation and the onset of loose stools. Dietetic upsets, infections of the upper respiratory tract and psychological disturbances are probably the important factors predisposing to the onset of diarrhoea.

The conclusion is that there is no evidence to support the view that severe cases of non-specific enteritis can be attributed to *Giardia intestinalis*. The suddenness of such outbreaks and the rapidity of spread suggests some bacterial or virus cause. [See also this *Bulletin*, 1943, v 40, 54, 699]

P Manson-Bahr

MOHAPATRA, G S *Giardiasis in Children* *Indian Med Gaz* 1948, Jan, v 83, No 1, 14-17

The report is based on 10 cases each of which is described separately. All the patients were children, of whom nine were under the age of 5 years.

Common symptoms were diarrhoea prostration—in proportion to the duration of the infection, although the children usually looked well—flatulence and poor appetite. The tongue was usually clean. Anaemia, in some degree was always noted [no records of blood examinations are given in the case notes so this was presumably a clinical observation]. There were frequent remission of symptoms usually coincident with some form of therapy.

The stools varied in colour and consistency but at some time in each case white fatty stools were passed in some cases this followed a period of bloody mucous stools. Motile *Giardia* *intestinalis* were found in large numbers in each case it was noted that in periods of remission the motility of the flagellates decreased.

Treatment by mepacrine (the author states atabrin or mepacrine) a quarter of a tablet 3 times a day for five days, effected a clinical cure in every case in two there was a temporary relapse which necessitated a second course. However in all cases the infection persisted for periods up to two months, although the flagellates were reduced in motility.

LIEBOW, A. A. MILLIKEN, V. T. & HANSEN, Clair A. Isospora Infections in Man. *Am. J. Trop. Med.* 1948, Mar. v. 23, No. 2, 281-73—pls. (44 refs.)

In 1933 MAGATH (this *Bullet.* 1933 v. 32, 600) summarized all information on this subject and since that time only one external clinical and parasitological study has appeared—this was a survey of German troops evacuated from North Africa by HERRLICH and LIEBOWITZ (ibid. 1944 v. 41, 782).

More than half the previously recorded instances had come from countries bordering the Mediterranean. Additional infections in man have been reported from China, N. and S. Africa, the Philippines, Argentina, Brazil, Russia, Palestine, Japan, Okinawa, Venezuela, Cuba and Mexico and other areas. The present paper deals with patients evacuated from the campaigns in the Pacific. One was apparently infected in the Solomons. Five other soldiers were sent to Saipan from Okinawa.

It is possible that intra-epithelial forms were seen by KILLBERG and described by VICHOW as early as 1890. It should be expected that *Isospora* would have an intracellular schizogamous cycle in analogy with other coccidia, but since the instance recorded above only the oocysts and their subsequent transformation leading to the development of four sporozoites in each of two sporocysts are known. GOTO has published evidence suggesting the existence of coccidiosis of the nasopharynx. The oocysts in all the present author's patients displayed the typical features of the genus *Isospora*. The length of the freshly passed oocyst at the commencement of segmentation is 31 μ with a width of 11 μ .

Development takes place *in vitro* even when the cysts are kept in hygroscopic solutions such as 2 per cent. potassium bichromate or saturated iron sulphate.

Under conditions of room temperature on Saipan the rate of segmentation of the sporoblast. The incidence of infection amongst soldiers evacuated from Okinawa was at least 0.5 per cent. and is similar to that of Herrlich and Liebmann's series.

Only one of the nine was omitted with actual diarrhoea but they had been a past history in three.

All but one had an eosinophilia (14 per cent. or higher) but only the leucocytes were also present in faeces and there is no evidence that this rise of leucocytes is due to the *Isospora*.

It is probable that signs and symptoms ascribed to infection with the organism are the result of coexistent infection with other organisms. It is

particularly difficult to assess the effect of therapeutic agents since the organisms tend to diminish and ultimately to disappear. There is no dramatic response to mepacrine, quinine, tetrachlorethylene or carbarsone.

An attempt was made to discover where the organisms may occur in the gastrointestinal tract. Miller-Abbott tubes were passed in all five patients and a sigmoidoscopic examination was made in each. Samples of intestinal contents were removed from the duodenum between 8 and 10 inches beyond the ligament of Treitz and at four other levels. Oocysts were found in the aspirated material in two patients.

P Manson-Bahr

MUKHERJEE, N N. Incidence of Coccidiosis in the Arakan. *Indian Med Gaz* 1947, Dec, v 82, No 12, 735-6 [12 refs]

Since the discovery of *Isospora hominis*, some 200 cases of infection by it have been reported, the highest figure in one zone being 32 from the Eastern Mediterranean. The author refers to previous records of cases in East Asia between 1920 and 1936, which varied between one and five in each locality quoted.

In the Arakan, on the Eastern frontier of South Bengal, the present author saw 14 cases of coccidiosis in about 7 months out of some 6,000 stool examinations from over 1,000 soldiers, British and Indian. Twelve of the 14 were detected by direct examination and the other two by Sheather's concentration method (sugar flotation). The findings are summarized in a table. Charcot-Leyden crystals were present in all but two cases. Most of the patients had loose, light-coloured stools with undigested food material. All cases occurred among British troops between May and October, the peak of incidence corresponding with the peak of the monsoon. Nearly all cases originated in the same area, suggesting some endemicity.

The condition was usually mild, and manifested by diarrhoea and some abdominal discomfort, but acute dysentery and prolonged illness of 3 to 5 weeks duration occurred in a few cases. Eight of the patients harboured some associated pathogenic intestinal parasites, such as nematodes or *Trichomonas hominis*.

RENS, M R. *Balantidium coli*. *Nederl Tijdschr v Geneesk* 1948, July 24, v 92 (III) No 30 2225-8, 2 figs on pl.

The English summary appended to the paper is as follows:—

Description of a case of very tenacious and frequent diarrhoea caused by *balantidium coli* a ciliate occurring in the intestine of man, pigs and monkeys. Our case concerned a pork butcher, who, owing to gross uncleanness very likely had infected himself with pigs *balantidia*. Morphology, morbidity, occurrence, reproduction and therapy of *balantidium* are further gone into.

Whereas the very numerous medicaments mentioned in the literature were not or only slightly successful in treating the disease, a speedy and complete recovery was brought about in the case described above by a 10 days' cure of 750 mg enterovioform 'Ciba'."

RELAPSING FEVER AND OTHER SPIROCHAETOSSES

COLLIER W A. Die Verbreitung der Leptospiren in Niederländisch-Indien [The Distribution of *Leptospirae* in the Dutch East Indies] *Acta Tropica* Basle 1948, v 5, No 2, 135-59.

Eighteen sorts of leptospirae have been isolated in the Dutch East Indies, and serological evidence has been found of the presence of 3 others. Of special

interest is *Leptospira bataviae* which was thought to have a very circumscribed distribution until it was reported from N. Itah (see MINO, *Bulletin JH gene* 1940 v 15 369).

The nomenclature of these leptospires presents difficulties. On the one hand, the same organism has been given different specific names by different authors while on the other certain workers believe that separation into species is not justifiable. Furthermore such words as type and group are used with a significance different from the meaning accepted in systematics. Collier holds that the antigenic structure of leptospires is constant, and that serological reactions should be used as the basis of classification. The species to which any strain belongs can be determined by agglutination-lysis tests. A species may however contain races which can be separated only by absorption tests. These have been called biotypes. In the case of *L. icterohaemorrhagiae* (GISEN & SCHIFFNER, *Zent f. Bakt. I. Abt. Orig.* 1939 v 144 427) but Collier suggests that they should rank as subspecies or Races—preferably the former. A list is given of the 4 species recognized by the author as being present in South East Asia. Details are set out of each type strain—host, place of isolation and original description—then follow any synonyms, and the distribution of the species in South-East Asia. [The information cannot be summarized.] Subspecies are noted for *L. autumnalis* (*L. autumnalis* and *L. a. rackmanii*), *L. latitans* (*L. latitans latitans* and *L. b. letal*), *L. icterohaemorrhagiae* (*L. icterohaemorrhagiae icterohaemorrhagiae* and *L. s. neumpleti*). One table shows the areas in South East Asia where human infections with the different species have occurred, another deal with survey of different animals, and records the numbers tested and the species of leptospires found in the different places. YAWS

GOODMAN L. Sudden Death after Intravenous Sodium Bismuth Tartrate. *Brit. Med. J.* 1948, May 22 978-9.

Previous reports indicate the toxicity of bismuth salts given intravenously and their action on the central nervous system and heart in animals. Despite the very extensive use of bismuth preparation in the treatment of yaws few fatalities have been reported.

Three African women were inadvertently given intravenously 10 grains (650 mgm.) of sodium bismuth tartrate (soluta) in aqueous solution. Two who had received 13 and 10 mgm. of soluta per kgm. body weight collapsed and were dead in minutes. Post mortem examination showed that the only notable abnormality was an unusual flabbiness of the heart. The cause of death was not recognized until the presence of bismuth in the liver was reported. None of the women had contraindications.

The third woman had received 11 mgm. of soluta per kgm. body weight and collapsed 8 minutes later. She was given narkothamide (1 ml.) and artificial respiration was applied. She recovered consciousness and was given Ardet and intravenous salines amounting not to 1 l. but because on the 7th appeared on the third day. Oliguria started early and resulted in anuria by the fifth day. After intravenous administration of a bismuth precipitant solution no details of dosage or of urinary excretion commenced and were used until on the 10th day when death occurred (total 450 ml.) were passed. All urine passed after the administration of the soluta contained albumin, red blood squacks and a little blood was present (was on 12) mgm. per 100 ml. on the last three days. Histological post mortem findings included

a marked blue gingivitis, a litre of clear, pale amber, peritoneal fluid, a soft enlarged liver with recent fibrinous adhesions to adjacent viscera and an inflamed lower colon and rectum with small petechiae. The kidneys were very pale and swollen, with complete destruction of the tubular epithelium and many granular and fatty casts. Kidneys and liver contained much extremely finely divided fat, otherwise the liver tissue showed little change. The relative quantities of bismuth per kgm liver tissue in the three cases were 40, 30 and 23 mgm respectively.

[How three, apparently consecutive, patients were inadvertently given intravenously doses of Sobita of three times the maximum intramuscular dose is not reported. No reference is made to any previous bismuth treatment these women may have received.]

LEPROSY

MARTINEZ DOMINGUEZ, V A proposito de la clasificación de la lepra [Proposals for the Classification of Leprosy] *Med Colonial* Madrid 1948 July 1, v 12 No 1 21-49 10 figs

A discussion on existing and proposed classifications

SCHUJMAN, S Tratamiento chaulmoógrico intensivo (intramuscular e intra-dérmico) en los casos lepromatosos no beneficiados con las dosis bajas de la misma medicación. Primeros resultados observados [Treatment of Lepromatous Forms of Leprosy with Large Doses of Chaulmoogra] *Prensa Méd Argentina* 1948, Mar 19, v 35, No 12, 501-5, 3 figs

The author, believing that the poor results of the treatment of leprosy were due to the smallness of the doses generally given, selected 30 patients suffering from the lepromatous form who had been under treatment for many years, some up to 10, on the usual doses of 30-50 cc a month. Of these only five had shown any improvement, 10 had remained stationary and 15 were worse. He started giving them larger doses of 90-150 cc a month. On the whole these doses were well tolerated, the local pain soon passed off and after eight months of this treatment none was worse, one only had remained stationary, 29 had improved, six of them "greatly improved". Photographs show the condition before starting the intensive course and at the end of it, the changes depicted are very marked.

H Harold Scott

FERNANDEZ, J M M & BERGEL, M Recentes investigações sobre o emprêgo metanal-sulfoxilato de sódio no tratamento de lepra [Formaldehyde-sulphoxylate of Sodium in the Treatment of Leprosy] *Hospital* Rio de Janeiro 1948, Apr, v 33, No 4, 549-52 [11 refs]

The authors argued thus for trying this drug. SOULE and MCKINLEY have shown that an atmosphere rich in oxygen affects cultures of [what they thought to be] *Mycobacterium leprae* [see this *Bulletin*, 1933, v 30, 238], GRAU TRIANA has shown the effect exerted by oxidases on such cultures [*ibid* 1945, v 42, 212]. The action of reducing agents on lower, unicellular organisms is different from that on the higher organisms, and therefore it may be possible to disturb [even destroy] the vital function of a pathogenic agent without injuring the body infected by the use of such agents.

Sodium formaldehyde sulphonylate ($\text{NaHSO}_3 \cdot \text{CH}_2\text{O} \cdot \text{H}_2\text{O}$) is a compound of sodium hydrosulphite ($\text{Na}_2\text{S}_2\text{O}_4$) and formaldehyde. The authors prepared a 10 per cent. solution of this drug in doubly distilled water and injected daily 6 gm. (0.5 cated) of it in two doses, intravenously and intramuscularly so as to keep the organism under continuous action of the drug. It was given thus for 10-15 days and renewed after an interval of 5-7 days. Given orally it was badly absorbed and caused diarrhoea. They treated 12 advanced lepromatous patients in this way and report favourably upon the drug—softening and diminution of the lepromata, diminution in numbers and staining properties of the bacteria. Later to assist the reducing action they gave ascorbic acid also but the results were no better in fact some seemed to recede. It is thought that in spite of the reducing action the ascorbic acid may in some way interfere with that of the metanal and sulphonylate.

Three hypotheses are put forward regarding the beneficial action of the drug. (1) That it is not specific but is merely a reducing agent. (2) That it acts as a specific poison in a certain stage of "vide reduction" [the *M. a. leprose*.] (3) That it acts as a poison on [presumably in relation with] some essential metabolism required by the organism. The authors hope to carry out more tests on a larger scale.

HELMINTHIASIS

GAUD J & MAURICE, A. Foyers de bilharziose fécale dans le Sous. [Foci of Urinary Schistosomiasis in the Sous Region.] *Bull. Inst. Hyg. Maroc* 1946 6: 81-2.

The existence of urinary schistosomiasis in the Wady Sous region of Morocco is confirmed. In three foci (Km. 44 Mt. Baha and Tanalt) the infestation rates in children in July 1947 were respectively 10, 9 and 86 per cent. The incidence seemed to be greater in the mountain (Anti Atlas) than in the plain. Malacological investigations were negative.

CRAW ELOISE B. [Studies on Schistosomiasis. Objectives of Research, Sources of Material, and General Methods.] *Nat. Inst. Health Bull. No. 163* Wash. 1947 49-54

The maintenance of a steady supply of material for schistosomiasis research in the United States was an essential part of the project designed primarily for the needs of the military forces and secondarily for the long range concerns of public health. The principal sources of material are listed. Supplies of eggs of *S. mansoni* were furnished for over 3½ years from *Leishmania* monkey which had been experimentally infected. Eggs of *S. haematobium* were obtained from a hamster permanently infected and from a fat tailed gerbil, *Meriones libicus* and *S. japonicum* were also experimentally infected. Eggs of *S. japonicum* were supplied by a Philippine dog. Small intermediate hosts were shipped from various sources either as adults or eggs.

The methods of shipment of snails, eggs, and subsequent treatment and the general methods employed in the laboratory for collecting schistosomes for and exposing snails to infection are described.

J. J. C. Buckley

LEIST, W H The Geographical Distribution and Molluscan Intermediate Hosts of the Schistosomes maturing in Man. Nat Inst Health Bull No 139 Wash. 1947, 1-25 [204 refs]

In this compilation "the schistosomes maturing in man" are restricted to the three well-known species *S. haematobium*, *S. mansoni* and *S. japonicum*, and the author reviews concisely the current position with regard to the validity and status of other less well-known or controversial species reported from human hosts. Doubtful or questionable distribution records of the three main species are discussed and considerable effort has been made to produce a complete and authentic list of localities.

The names of molluscan intermediaries are listed with the localities, together with annotations relating to their nomenclature, and status as authentic or merely inferential hosts. The list of 201 references is classified under geographical headings. J J C Buckley

BERRY, E G Snails collected for the Schistosomiasis Investigations Nat Inst Health Bull No 189 Wash. 1947, 55-69, 1 fig on pl.

Collections of snails for schistosomiasis research in the United States were made by the author from 11 States: Michigan, Kentucky, North Carolina, South Carolina, Georgia, Florida, Mississippi, Louisiana, Texas, Utah and California. Particular attention was given to the collection of members of the family Amnicolidae, of which the genus *Oncomelania* is a member.

From more than 150 localities in these States, 54 species of Amnicolidae, Pomatiopsidae and Planorbidae (including the genus *Tropicorbis*) were taken. The species in this collection are listed together with those of another collection. In all, 103 species and sub-species were identified, representing nine families of molluscs. J J C Buckley

CRAM, Eloise B, FILES, Virginia S & JONES, Myrna F Experimental Molluscan Infection with *Schistosoma mansoni* and *Schistosoma haematobium* Nat Inst Health Bull No 189 Wash. 1947, 81-94 [25 refs]

The authors exposed 23 species and subspecies of native American snails to the family Planorbidae and 4 species of non-planorbids to infection with the Puerto Rican strain of *Schistosoma mansoni*. The only susceptible species found to be *Tropicorbis havanensis* (Pfeiffer), which produced cercariae infective to mice. Exposure of American snails to infection with *S. haematobium* gave negative results but the authors comment upon their lack of success in infecting *Bulinus contortus* and *Physopsis africana* with *S. haematobium*. J J C Buckley

GELFAND, M Bilharzial Affection of the Ureter A Study of 110 Cases of Necropsies showing Vesical Bilharziasis Brit Med J 1948, July 1228-30 [10 refs]

The ureter is often affected in bilharziasis. In 110 consecutive post-mortem examinations in Salisbury, Southern Rhodesia, on adult Africans from an endemic bilharziasis area, ureteral dilatation was found in 25 cases, three had ureteral strictures. In 16 of the 25 the dilatation was unilateral [below], in 6 of these it affected the whole length of the ureter, in 5 the dilatation was unilateral (sic), [? bilateral], in 2 of these the whole of the ureter was involved, in 4 the middle third, and in 3 the middle third. (1031)

The diseased portions of the ureter are readily identifiable by changes in their colour, texture and appearance. These were usually found in the lower third. No dilatation occurred in the absence of such changes. If the cause of the dilatation was stenosis it would be expected that the whole of the ureter above the constriction would be dilated, and the dilatation would not be confined to the site of the disease as was found to be the case. The dilatation is therefore directly attributable to damage to the ureteral wall by the disease. The disease is thus associated with ureteral dilatation but rarely with stenosis as has previously been thought. The dilatation and thickening of the ureteral wall lead to impaired peristalsis with stasis, and possibly reflux of urine from the bladder. These in turn cause hydronephrosis.

Eight cases of hydronephrosis were encountered, and 4 of these in which the condition was bilateral showed ureteral dilatation. One case of these four was attributable to a congenital abnormality of the ureteric openings in the bladder. In one case of ureteral stenosis there was hydronephrosis on the same side as the stricture. In 2 of the 3 cases with ureteral stenosis there was no hydronephrosis. Three cases of carcinoma of the bladder were associated with bilateral hydronephrosis, due to lower ureteral obstruction by the growths.

Histological sections of the bilharzial disease in the ureters showed ova to be present in the submucosa and between the muscle bundles in the muscular layer. Tubercle formation so common in the appendix, was not seen. The separation of the muscle fibres results in their atrophy, and the affected portion of ureter becomes dilated, elongated and tortuous. The changes in the ureteric orifices in the bladder were inconstant but in no case was there true stenosis with occlusion.

IBRAHIM, M. SOLOUBI, A. & EL-SHERIF, A. The Role of Urinary Bilharziasis in the Production of Hypertension and Cardiac Decompensation. *J. Roy. Egyptian Med. Ass.* 1948 May v 31 No 5 444-62. (10 refs.)

The authors review their findings in 89 cases of hypertension (57 essential and 32 nephritic). Four (7 per cent.) of the cases of essential hypertension had associated urinary bilharziasis. 13 (40.8 per cent.) of those with renal hypertension had evidence of the disease. 8 (18.7 per cent.) other cases were considered probably to be of bilharzial origin. Secondary infection of the kidneys following a urinary bilharzial infection leads to renal hypertension if this is due to a one-sided lesion nephrectomy may be considered.

CRAM, ELOISE B. & FILES, VIRGINIA S. Experimental Mammalian Infection with the Schistosomes of Man. I. Laboratory Animals as Source of Supply of Adult Schistosomes and their Ova. *Nat. Inst. Health Bul.* No. 189 Wash. 1947 101-5

Attempts to establish and maintain the three species of schistosomes of man in laboratory animals were successful in the case of *S. murici* and *S. japonicum* but not with *S. haematobium*. Monkeys were infected with cercariae of *S. mansoni* from Australia & glabra by the method which are described but their relative effectiveness could not be determined. Subcutaneous injection of *S. mansoni* cercariae into dogs gave normal results. From various trials with smaller laboratory animals it was concluded that the best results derived from intraperitoneal injection of mice and hamsters. Dogs were found to be excellent hosts for *S. japonicum* and golden hamsters and white mice were also found to be good hosts in the case of infections of the latter animals. The mortality was high in the prepatent period. J. J. C. Finkler

CRAM, Eloise B & FIGGAT, W B **Experimental Mammalian Infection with the Schistosomes of Man II Comparative Study of *Schistosoma mansoni* and *Schistosoma japonicum* Infections produced by Immersion and by Intraperitoneal Injection** *Nat Inst Health Bull No 189* Wash 1947, 106-8

Hamsters were exposed to infections either by immersion or by injection with known numbers of cercariae, in two experiments in which *S. mansoni* and *S. japonicum* were used respectively. With *S. japonicum*, 49 per cent of the cercariae developed as the result of the immersion method and 51 per cent by the injection method. With *S. mansoni* 33 per cent of the cercariae developed from the immersion method and 19 per cent from the injection method.

J J C Buckley

OTTOLINA, C **El problema clinico de la Schistosomiasis Mansoní ante nuevos metodos diagnosticos y sus resultados [New Diagnostic Methods for Schistosomiasis Mansoní]** *Medicina Mexico* 1947, Dec 25, v 27, No 546, 553-64 [27 refs]

The author in dealing with this clinical problem offers a few remarks on treatment, but these contain nothing new and the main part of the paper is on the question of diagnosis. He quotes various reports showing that examination of the faeces yields but a comparatively small proportion of patients actually infested, from 2 to 9 per cent. Rectal biopsy, however, demonstrates some 20 per cent. Even when the ova are present in the rectal tissues in large numbers ("many thousands" says the author) they may not pass into the lumen and so not appear in the faeces, in short, the absence of ova in the faeces is no proof that *Schistosoma* infestation does not exist. Even a positive rectal biopsy does not prove active disease unless the ovum seen contains a living miracidium. Another advantage of the method is the diagnosis of latent or asymptomatic schistosomiasis and of extinct infestation. Cases, he states, may be divided into four groups: (1) *True latent infestations*, the worms being alive and the ova some living, some dead, but there are no clinical signs or symptoms. (2) *Latent extinct*, the worms have died recently and a few living ova may still be present, again without symptoms. (3) *Active disease*, live worms, live eggs and symptoms present. (4) *Extinct infestation*, worms dead and no live ova seen even after repeated examination.

H Harold Scott

WARD, P A, TRAVIS, Dorothy & RUE, Ruth E **Methods of establishing and maintaining Snails in the Laboratory** *Nat Inst Health Bull No 189* Wash 1947, 70-80, 2 figs

The methods employed in maintaining in aquaria amnicolid snails known to serve as intermediaries for *S. japonicum*, are described in detail, together with observations on their breeding habits in the laboratory. *Oncomelania quadrasi* bred satisfactorily in the conditions described but the propagation of *O. nosophora* and *O. hupensis* was more limited.

J J C Buckley

WARD, P A, TRAVIS, Dorothy & RUE, Ruth E **Experimental Molluscan Infection with *Schistosoma japonicum*** *Nat Inst Health Bull No 189* Wash 1947, 95-100

Twelve species of American snails, of the family Amnicolidae, were exposed to infection with *Schistosoma japonicum* in 1945, and five species of Amnicolidae and Pomatiopsidae in 1946. One species, *Littoridina monroensis*, proved to be particularly attractive to miracidia, but failed to develop sporocysts. Of 286

specimens of the poecis *P. watsoppsi lapidaria* which were exposed, 8 developed sporocysts resembling those of *S. japonicum* but this result is regarded as inconclusive. Control experiments with *Oncomelania nasophya* generally produced positive results.

J J C Buckley

JONES, Myrna F & BRADY F J. Survival of *Schistosoma japonicum* Cercariae at various Temperatures in several Types of Water. *Nat. Inst. Health Bull* No. 182 Wash. 1947 131 & 1 fig.

The authors noted experimentally the following death points for cercariae of *S. japonicum*: 4 hours at 40°C, 20 minutes at 45°C, 3 minutes at 50°C, and one minute at 55°C. With cercariae of *S. mansoni* the results were: 20 minutes at 45°C, 2 minutes at 50°C, and 1 minute at 55°C.

Within the range 15°C to 40°C, the survival of the cercariae of *S. japonicum* decreased as follows: At 5°C, a few survived 8½ but none survived 10½ days; at 10°C, some survived 4½ but none survived 6½ days; at 20°C, and 25°C, some survived 2 days, but none survived 3 days; at 30°C the maximum survival observed was 22 hours; at 40°C, some survived 3 hours but none survived 4 hours.

The survival of cercariae at temperatures ranging from 5°C. to 35°C. in a variety of waters was also tested: namely ammonia free distilled water buffered at pH 7.0 to 7.1; a slightly alkaline raw surface water obtained from a filter plant; a more alkaline water from a pool containing dead leaves and their plant debris; a raw water acidified by contact with peat moss; and water from aquaria in which stock snails, *Oncomelania quadrasi* were living. The pH of the more acid water was 5.5 to 6.5 and that of the other raw waters 7.2 to 8.4. It was found that the survival of the cercariae at each temperature was the same in all the raw waters irrespective of different pH values. Their survival in buffered distilled water at 20°C, 25°C and 30°C was the same as in the raw waters but was less at 5°C and rather longer at 35°C.

J J C Buckley

BOZICAVICH J & HOVEN, Helen M. Intradermal and Serological Tests in Patients with *Schistosomiasis Japonica*. *Nat Inst. Health Bull* No. 182 Wash. 1947 199-212.

Intradermal and complement fixation tests were conducted on a group of 474 patients demonstrated to have or to have had *schistosomiasis japonica*. The antigens were prepared from cercariae and adults of *S. mansoni*. Intradermal tests with an antigen prepared from cercariae gave fewer falsely positive reactions with unexposed control individuals than did antigen prepared from adult worms. The use of adult worm antigen resulted in a higher percentage of positive intradermal reactions than did the cercarial antigen. The complement fixation test gave a higher percentage of positive reactions than did the intradermal test. The optimal dilution of the cercarial antigen could not be determined because of insufficient material.

"The result of both the intradermal and complement fixation test gave better correlation with results of the stool examination conducted in the United States than they did with those conducted overseas. Early detection therefore may be the factor which would explain the discrepancy in these results."

"Because of the conditions under which this investigation was conducted, the immunological findings probably be less reliable than did the stool examinations in the diagnosis of the disease."

"For this reason improvement will have to be effected in immunological methods before such tests can be reliably employed in diagnosis."

JONES, Myrna F, NEWTON, W L, WEIBEL, S R, WARREN, H B, STEINLE, Mary L & FIGGAT, W B **The Effects of Sewage Treatment Processes on the Ova and Miracidia of *Schistosoma japonicum*** *Nat Inst Health Bull No 189* Wash 1947, 137-72, 1 fig

The sewage treatment processes which are considered in this report in relation to their effect in destroying schistosome eggs and miracidia or in relation to their effect in concentrating eggs and miracidia in streams which might contain potential snail hosts, include the following Primary sedimentation, anaerobic digestion of sludge, air drying of sludge, the activated sludge process, filtration with a trickler filter, and intermittent sand filtration After a discussion of sewage and sewage treatment generally, with special emphasis on the processes concerned in the investigation, the technique and procedures employed in testing their effect on eggs of *S japonicum* are described in detail

Primary Sedimentation—From tests carried out in a 19-inch column of sewage it was found that quiescent sedimentation for 5 minutes removed 25 per cent of the eggs, 10 minutes, 47 per cent, 30 minutes, 80 per cent, 1 hour, 97 per cent, and two hours, 98 per cent The settling rate was estimated as varying between 0.33 and 1.4 inches per minute Although some eggs could escape with the effluent in primary tanks, it is concluded that the majority would be removed by primary sedimentation during the normal detention period

It was found that raw and institutional sewage would not permit hatching in 24 hours but did not destroy the eggs in this time In a dilution of one part of raw sewage to three parts of water, or one part of settled sewage to two of water the eggs would hatch

Anaerobic sludge digestion—Experiments were set up to determine how long the eggs could survive in the sludge digestion sections during this process At 75° to 85°F during the first week, about $\frac{1}{4}$ of the eggs were rendered incapable of hatching This reduction continued during the second week and was greatest in the third week and there was no hatching on the 24th day of digestion It is believed, however, that the temperature and time factors played a large part in this reduction in the viability of the eggs

Sludge drying—In drying digested sludge many eggs were mixed and allowed to dry for varying periods It was found that the retention time on the drying bed was more closely related to destruction of the eggs than was the moisture content, so long as the latter was 40 per cent or over Thus, sludge which is to be dried to 60 or 70 per cent moisture content before disposal would need to be retained for 3 weeks to ensure the destruction of any eggs which might be present

Trickling filter treatment—This secondary treatment of the effluent from primary sedimentation tanks which sometimes may carry over with it schistosome eggs, was tested in relation to its effect on the eggs It was found that filtration reduced the number of eggs but in all experiments some got through Secondary settling of the effluent reduced these but failed to remove them entirely In such conditions additional treatment such as chlorination is indicated

Activated sludge—Experiments were set up to determine the survival of schistosome eggs in activated sludge Hatching of most of the eggs occurred in the first 24 hours and very few miracidia were recovered after 3 days, indicating that the activated sludge is an excellent hatching medium A post-treatment process designed to destroy or remove miracidia is again indicated.

Intermittent sand filtration—In five experiments, employing this process, in which the rate was 100,000 gallons per acre, per day, sand with an effective size of 0.3 mm and a uniformity coefficient of 2.6 being used, it was demonstrated to be an efficient method of removing eggs of *S japonicum* from sewage

Aerosol OT (dioctyl sodium sulphosuccinate) —The tests showed that only in relatively concentrated solutions was this compound effective but that in non-lethal concentrations it might enhance or accelerate the effects of other cercaricides

Copper sulphate —Tested in concentrations of 5, 10 and 50 p p m, it proved effective only at 50 p p m, or more. It could not be relied upon at 5 or 10 p p m to kill cercariae within a reasonable time

DDT in emulsion with Triton and xylene —In limited tests this proved to be not an effective cercaricide in concentrations of 0.05 and 0.1 p p m, but at 10 p p m killed cercariae within 75 minutes

J J C Buckley

JONES, Myrna F & HUMMEL, Mirtiel S. The Effect of Chlorine and Chloramine on Schistosome Ova and Miracidia. *Nat Inst Health Bull No 189* Wash 1947, 173-9

"Hatched miracidia of *S. japonicum* were killed within 30 minutes after chlorination with total 30-minute residuals of 0.2 and 0.4 p p m. Similarly, they were killed in chloramine solutions with 30-minute chloramine residuals of 0.3 and 0.4 p p m. *S. mansoni* miracidia were killed within 30 minutes after chlorination which resulted in total residuals at 30 minutes varying from 0.2 p p m to 0.6 p p m and less than 0.1 p p m free chlorine present.

"Ova of *S. japonicum* are more resistant to chlorination than are miracidia. Ova were consistently killed within 30 minutes only in tests in which the 30-minute total residuals varied from 3.9 to 11 p p m.

A few ova survived 2-hour treatment with chlorine and chloramine concentrations of 1.52 and 1.65 p p m and 30-minute residuals of 0.75 and 1.1 p p m respectively. No ova survived in one test after an applied chloramine concentration of 1.9 p p m and a 2-hour chloramine residual of 0.5 p p m. Ova were killed in tests with an applied chlorine of approximately 2 p p m and 2-hours residuals varying from 0.7 to 1.4 p p m."

NOLAN, M O, MANN, Elizabeth R & CHURCHILL, Helen M. The Protective Value of Chemically Impregnated Fabrics against Penetration of Schistosome Cercariae. *Nat Inst Health Bull No 189* Wash 1947, 180-98, 1 fig

Standard army uniform materials were used in tests to determine the relative value of chemically treated fabrics as a means of protection against the penetration of schistosome cercariae. Seventy-five chemical compounds, including combinations of chemicals and emulsions, were used to impregnate fabrics and were tested for toxicity to cercariae. The tests were conducted at intervals after repeated rinses of the treated fabrics in water. Mouse exposure tests were subsequently conducted to determine the protective value of those chemicals that in the preliminary tests were most effective against cercariae and most resistant to water rinses. More than 2,000 mice were exposed to cercariae in the testing of 18 chemical compounds and emulsions used to impregnate cotton herringbone twill fatigue uniform cloth, khaki cotton uniform twill and khaki woolen serge cloth. Since water solubility of the impregnated compounds was an important factor, the majority of the mouse exposure tests were conducted at intervals after repeated rinses of the fabrics in water. Fabrics impregnated with emulsions of the cercaricides were also tested for resistance to mild laundering with soap.

The most effective chemical was N,N-diethylauramide which protected mice against penetration of *S. mansoni* cercariae through at least 144 hours of rinse and afforded considerable protection even after 180 hours of rinse. The emulsion of the compound, however, was one of the least resistant to washes

with soap. The compound in acetone solution appeared to be more resistant to soapy washes than the emulsion of the compound.

"Dibutyl phthalate was somewhat less effective but provided protection for more than 96 hours of rinse. The emulsion of the compound was more resistant to soapy washes than was *N,N*-diethylauramide emulsion since it lasted through five washes.

Tests with *S. japonicum* cercariae were less numerous than those with *S. marginata*. However it would appear that the two species reacted in the same manner to treated fabrics.

A measure of protection was afforded by the untreated materials. Woolen serge cloth in particular was a good mechanical barrier."

McMULLEN D. B. & BRACKETT S. Studies of Schistosoma Dermatitis. X. Distribution and Epidemiology in Michigan. *Amer J Hyg* 1948, May v 47 No 3 259-70 2 figs.

In a survey of schistosome dermatitis in Michigan, 510 beaches on 177 lakes have been examined. Of these, 351 were found to have populations of carrier snails. On 130 beaches it was possible to demonstrate the presence of the infections in the snails collected. In others, infections undoubtedly could have been found at certain times of the year when adult snails were present.

"The distribution of *S. marginata* has been thoroughly investigated. It is most common in the northwest part of the Lower Peninsula and in the eastern section of the Upper Peninsula, and it is the most important vector for water itch in Michigan. In a few areas *Physa* spp. have been shown to be the cause of outbreaks and in 3 or 4 lakes *L. stagnalis* was suspected of being the source of the trouble. In all of the beaches examined the 3 snails, *S. marginata*, *Physa* spp. and *L. stagnalis* appear in the ratio of "1" "1" and the ratio of the infected snails was found to be 39:3:1. These ratios indicate quite well the relative importance of the 3 snails in the water-itch problem in Michigan. Water itch is found primarily in the northern part of the Lower Peninsula and the eastern portion of the Upper Peninsula. This coincides with the density of the *S. marginata* populations. The sporadic cases that appear in other parts of the state apparently are caused by schistosome cercariae coming from *Physa* spp. and *L. stagnalis*.

VON BOASDORFF B. Pernicious Anemia caused by *Diphyllobothrium latum*, in the Light of Recent Investigations. *Blood* 1948, Jan., v 3, No. 1 91-102. [29 refs.]

In Finland infestation with the fish tape worm, *Diphyllobothrium latum*, is extremely common, in certain Provinces more than 90 per cent of the population being infested. In most carriers the worm is a relatively innocent parasite but in some it causes a macrocytic anaemia resembling pernicious anaemia although differing in its age incidence, the absence of achlorhydria in many cases and the absence of neurological involvement. That the anaemia is due to the worm seems proven by the fact that the anaemia undergoes complete remission after the worm is expelled, without any further need for anti-anæmic treatment. There seems no doubt that the worm contains a powerful toxin, and theories to explain the anaemia have included absorption of the intestinal wall to worm toxin, individual susceptibility of the haemopoietic system to the toxin or an allergic factor. Complete recovery from the anaemia after the worm has been expelled implies that there is no lack of haemopoietic principle. Experiments have shown that the gastric juices of patients with fish tape worms contain intrinsic factor and the anaemia may occur even though the food

contains extrinsic factor, although a relative deficiency of extrinsic factor may aggravate the disease. The clinical picture gives no reason to believe that absorption is impaired, carriers of the worm seldom suffer from intestinal disturbances and glucose tolerance tests showed no deviation from the normal. Powdered worm mixed with gastric juice, meat or hog's stomach failed to destroy the anti-anaemic action of these preparations in pernicious anaemia. It is suggested that possibly any inhibition of interaction between intrinsic and extrinsic factors can only be produced by the living worm in its natural surroundings at the place where interaction occurs. By intestinal intubation and examination of aspirated material for eggs, evidence was obtained that with anaemia the worm is found higher up in the intestine than when anaemia is absent, and it is suggested that in the higher regions, the worm interferes more with the interaction between extrinsic and intrinsic factor, the border zone lies 140 to 150 cm from the mouth, namely about the junction of the jejunum and ileum [See also this *Bulletin*, 1948, v 45, 97, 198, 260]

LE GAC, P. Toxicité des sels d'étain vis-à-vis des plathelminthes [Toxicity of Salts of Tin to Tapeworms] *Bull Soc Path Exot* 1947, v 40, Nos 11/12, 452-5

The author presents observations on several cases of Taeniasis which were successfully treated with stannous oxide (Stannoxy)l. He gave 6 to 8 tablets daily and the worms were expelled in 2 to 6 days. The author also mentions a proprietary vermifuge prepared from salts of tin and metallic tin which gave similar results. The preparation is sold under the name of "Taenifuge Ercé" (Laboratoires Rabent et Carrière). It is stated to be absolutely harmless and keeps well for long periods in the tropics. In a discussion, MONTEL confirmed successes with Stannoxy, which he gave in doses of 18 tablets daily (6 morning, noon and evening). No purgative, special regime or bed rest was required.

BALDWIN, E. A Study of Anthelmintic Potency in relation to Chemical Constitution. *Brit J Pharmacol & Chemotherapy* 1948, June, v 3, No 2, 91-107 [30 refs]

The author tested 200 chemical compounds for detection of anthelmintic potency. Pig *Ascaris* was the test helminth used, and it is claimed that, while

the technique used has certain limitations, it is important that experimental material of nematode origin should be the basis of methods of this kind.

The results are discussed in great technical detail and should be studied in the original but they were at variance with those of earlier investigators in most respects, especially in respect of lactones. More than 30 types of lactones were tested by the author but not one showed activity comparable with or even approaching that of santonin (itself a lactone). This contrast with the findings of other workers is attributed by the author to the use of different & two methods many of the observations reported in the literature have been prejudiced, in the author's opinion by the use of annelid material.

DE REYES PLUVAIRE, M. Tratamiento de la elefantiasis de los miembros inferiores. (Treatment of Elephantiasis of the Legs.) *Med. Comunal* Madrid. 1948, June 1 v 11 No. 6 441-63 13 figs. [75 refs.]

The author reviews the various methods of treatment of elephantiasis of the legs, referring first to medical treatment, later and in more detail to surgical measures. He mentions first antistreptococcus serum and states that he has obtained good results if there is inflammation present with vaccines he reports very good results especially in accessions of elephantoid fever. He quotes records of others such as antobaemotherapy gentian violet fibrolysin iodides sulphonamides in the fever but makes no mention of having tried these on his own patients and notes that in most cases any benefit had been only temporary. During attacks of fever he employs at the same time sulphonamides, local warmth and an ointment of ichthyol 15 gm., Tr. iodii 15 gm., camphorated oil 30 gm. with compressing bandages.

He then passes on to describe operative treatment in particular detail Honduran's operation and modifications of it. He sketches the history of operative measures and then gives a fuller account of his modification of the operation with illustrations to indicate the steps, and photographs showing the intermediate and final results. He removes the fascia and ponsorus of the legs and the dorsum of the foot with extensive dissection. In some cases a second and even a third operation are needed, but the results as depicted are in some cases at least remarkably good. After the operation he dusts with sulphonamide powder then stitches the skin without any drainage. He quotes records from the Mayo clinic giving a mortality of 4.7 per cent., and "satisfactory results" in 62 per cent.

The author gives a table of 7 patients under his care the methods of treatment are stated, but not the results. Of the total 14 were treated medically and 33 had some operation, 10 the P y r Honduran's trunk, 20 the author's method with previous resection of the muscle fascia (three had, in addition to this on account of chronic ulcer a preliminary lumbar sympathectomy) 10 had extensive removal of tissue on both the front and back of the leg. He concludes that medical treatment is of much importance as an adjunct and as preparatory to surgical measures.

MAZZOTTI, L. Observaciones sobre la oncocercosis en México. (Observations on Onchocerciasis in Mexico.) *Medicina* Mexico 1948 June 10 v 28, No. 557 17-24. 18 refs.

Onchocerciasis prevails in Mexico at heights of 400-1,200 metres above sea-level and chiefly in the States of Chiapas and Oaxaca, which are sub-tropical with a heavy rainfall. The vector is *Simulium ochrocephalum* *S. castaneum* and *S. mexicanum* especially the first which breeds in small collections of water moving slowly the two other prefer larger collections moving rapidly.

In man the nodules are often in the head, less often in the thorax and lumbar region, and usually up to six in number, but they may be many more. In 34 patients, 325 biopsies were performed. 52 per cent of nodules were on the face (or head), 65 on the shoulder, 52 on the forearm, 39 on the hand, 44 on the thorax, 34 on the thigh and 16 on the foot. From one patient with a thigh nodule an inguinal [? femoral] gland was extirpated and 11 microfilariae were expressed from it. The skin may become of a dark greenish colour, in fact, it is known in Mexico as "mal morado" (purple disease). Sometimes allergic attacks occur with fever and local induration so that in time the skin becomes thick and hard, "woody", these attacks are known in Guatemala as "Coast erysipelas".

Treatment is by Hetrazan, which is 1-diethylcarbamyl-4-methyl piperazine hydrochloride, in doses of 2 mgm per kilo body weight, once on the first day, twice on the second, and thereafter three times daily for 3 weeks or more. Some of the author's patients took it for 6½ weeks, but, as tested by biopsy, the results after the longer course "were not appreciably better than after the shorter" [See also this *Bulletin*, 1948, v 45, 532, 533] H Harold Scott

SPRUE

SPIES, T D, GARCIA LOPEZ, G, MILANES, F, LOPEZ TOCA, R & CULVER, Belle
Observations on the Hemopoietic Response of Persons with Tropical Sprue to Vitamin B₁₂ *Southern Med J* 1948, June, v 41, No 6, 523-5

In 1947 SHORR (*J Biol Chem*, 1947, v 169, 455) found in refined liver extracts a growth factor required for *Lactobacillus lactis* (LLD factor) which was present in an almost linear relationship to the unit potency of the extracts used in the treatment of pernicious anaemia. This is probably identical with a crystalline compound, vitamin-B₁₂, and is believed to be partly responsible for LLD growth activity observed for liver extracts (RICKES *et al*, *Science*, 1948, Apr 16, 396). The positive response in pernicious anaemia as the result of small amounts administered to patients compared favourably with those obtained with folic acid and 5-methyl uracil (thymine), but neither of the latter has been found to prevent, or relieve, subacute combined degeneration of the spinal cord. It is with the effect of crystalline B₁₂ in patients with tropical sprue that the present communication is concerned.

The two patients with tropical sprue who were selected conformed to the criteria which have been laid down —

- (1) There was macrocytic anaemia with a red blood cell count of 2.5 million, or less, and a colour index of over 1,
- (2) the bone marrow contained megakaryoblasts and had the typical erythroblastic arrest seen in macrocytic anaemia,
- (3) the diarrhoea was characterized by fatty stools,
- (4) glossitis and weight loss were present, and
- (5) the patients were otherwise untreated.

When the patients were placed on a diet devoid of meat, fish, poultry, milk and eggs, basic studies were completed and each was given a single dose of 0.008 mgm crystalline B₁₂ intramuscularly.

the technique used has certain limitations, it is important that experimental material of nematode origin should be the basis of methods of this kind.

The results are discussed in great technical detail and should be studied in the original but they were at variance with those of earlier investigators in most respects, especially in respect of lactones. More than 30 types of lactones were tested by the author but not one showed activity comparable with or even approaching that of santonin (itself a lactone). This contrast with the findings of other workers is attributed by the author to the use of different *in vitro* methods many of the observations reported in the literature have been prejudiced, in the author's opinion by the use of animal material.

- (3) The diarrhoea was characterized by fatty stools.
- (4) The patients and weight loss were present.
- (5) The patients were otherwise unselected.

When the patients were placed on a diet devoid of liver, poultry, fish and eggs these studies were completed and each was given a single dose of 0.005 mg crystalline B₁₂ intramuscularly.

In both patients (Cubans of 62 and 67 years) on the third day the soreness had disappeared from the mouth and tongue the appetite had returned the volume of the stools had decreased and they were less gaseous. On the sixth day the patient volunteered the information that they felt "wonderful."

The reticulocyte rise occurred on the fifth day and rose to a peak on the eighth.

P. MARRAS-BLIER

HAEMATOLOGY

WILLS, Lucy. Pernicious Anaemia, Nutritional Macrocytic Anaemia, and Tropical Sprue. A Discussion. *Blood* 1948 Jan. v 3 No. 1 33-56. [83 refs.]

Anaemia is only one aspect of pernicious anaemia nutritional macrocytic anaemia and tropical sprue the three diseases presenting fundamental differences which tend to be overlooked because of the similar response of the conditions to treatment with liver extracts or folic acid. Pernicious anaemia is a familial disease of persons of European descent the distribution of the disease corresponding to that of the racial groups affected, but occurring in all social classes of individuals. There are atrophic changes in the fundus and cardia of the stomach, with associated achylia gastrica an increased plasma bilirubin the presence of methaemalbumin in the plasma iron in the faeces and other evidence of a haemolytic factor and frequently subacute combined degeneration of the cord. The disease including the neural changes, can be successfully treated with crude or purified liver extracts given parenterally or orally with proteolysed liver extract by mouth with different preparations of horse stomach by mouth and with digests of beef muscle or autolysed yeast with normal human gastric juice. Folic acid and its conjugated forms produce haematological remission often suboptimal and an immediate sense of well-being but they are without benefit on the cord changes.

Nutritional macrocytic anaemia occurs mainly in tropical and subtropical areas, but the disease is associated with poverty with a low caloric largely or entirely vegetarian diet with pregnancy and lactation and with certain diseases, such as syphilis or particularly chronic malaria, which result in a hypertrophied reticulo-endothelial system. There are no significant consistent changes in the gastric mucosa or secretion. There is no evidence of increased haemolysis except in areas with a high incidence of malaria. In the haemolytic type there are increased serum bilirubin values, a positive Schumm test an increased urobilin output, yellow coloration of the skin and fat plenomegaly and sometimes hepatomegaly and histological evidence of a hypertrophied reticulo-endothelial system. Both the non-haemolytic and haemolytic types of the disease respond to crude liver extracts given orally or parenterally and to autolysed yeast extract. Relapses do not occur after cessation of treatment if the diet is maintained at a satisfactory level. Folic acid acts as in pernicious anaemia. The haemolytic type as in Macdonald's is sometimes very resistant to treatment but some cases respond to enormous doses of liver extracts or Marmitt.

Sprue has usually a gradual onset and is associated with residence in warm climate but affects Europeans rather than pure Indians or Negroes. Many of the patients have been well fed and there is little evidence for direct nutritional origin for the altered intestinal absorption which conditions the ultimate deficiency. The disease is normally chronic throughout but a definite infective origin has been suggested by certain pleomorphic and locally concentrated outbreaks which have occurred. Lesions of the central nervous

system do not occur and apart from changes in the bone marrow and general inanition with decrease in organ weight, especially of the heart and liver, there are only slight anatomical changes detectable at autopsy. The disease responds to a high protein diet with liver extract or folic acid. Blood transfusion in the critically ill and sulphaguanidine where there is excessive diarrhoea may help.

In all three conditions, the classic picture of panhaemopoietic dystrophy is present, it is characterized by a megaloblastic erythropoiesis, a similar disturbance in the myeloid series with pathological macro-myeloid cells, and reduction and abnormality of thrombocytes. The general opinion is that the changes in the cells of the marrow and blood are identical in the three diseases. The panhaemopoietic dystrophy possibly results from a breakdown of an intracellular enzyme system, but the deficiencies causing the breakdown differ. In pernicious anaemia there is a genetic fault which results in a persistent and irreversible failure in the formation or absorption of the liver factor, and possibly of a neurotrophic factor. In endemic nutritional macrocytic anaemia there is an unconditioned food deficiency, the deficiency being in a factor other than the liver principle, possibly a co-enzyme present in or associated with good biological protein and the vitamin B₁₂ complex, in areas of high malarial incidence a haemolytic factor may also be present. Tropical sprue is associated with a functional disorder of the intestine, possibly a failure in phosphorylation of fatty acids, glycerol and glucose, but the cause of this functional breakdown is unknown.

F Murgatroyd

TROWELL, H. C. Tropical Macrocytic Anaemia and Nutritional Macrocytic Anaemia. *South African J Med Sci* 1947, Jan, v 12, No 1, 21-31 [57 refs]

There appears to be no valid distinction between macrocytic anaemia associated with pregnancy and nutritional macrocytic anaemia not associated with pregnancy. Similarly, there appears to be no real distinction between the macrocytic anaemia of pregnancy in warm climates and that of temperate regions. Some confusion arises because the blood and bone marrow have not always been clearly described in tropical anaemia and because many of the tropical cases are complicated by a light helminthic infection or mild relapsing malaria. In the present paper, the author analyses 63 cases of anaemia, of which 6 were associated with pregnancy, in Uganda. The aetiology of the anaemia in most of the cases was multiple, 80 per cent of the patients harbouring hookworms and 31 per cent showing malaria parasites. Most patients had a dual deficiency of iron and liver principle, giving rise to a dimorphic anaemia. Such an anaemia can often be determined from the appearance of a carefully spread thin blood film. With a dual deficiency, the film presents neither the picture of hypochromic cells with little anisocytosis such as is seen with pure iron deficiency, nor that of evenly stained flattened cells with much anisocytosis such as is characteristic of a pure deficiency of liver principle. In films of dimorphic anaemia, the central fields show solid-looking cells, perforated with one or more vacuoles, interspersed with a few densely stained thickened cells, and moderate increase of anisocytosis, while the peripheral fields show a few thickened cells and many flat cells, which are evenly stained, and there is increased anisocytosis. It might be expected that macrocytic orthochromic anaemia should, like pernicious anaemia, react to liver but not to iron, but out of 24 cases tested with crude liver extracts, 3 showed no response and 19 responded, whereas out of 14 cases tested with iron, 6 responded very well, 4 responded fairly well and 4 showed no response. In like manner, neither normocytic nor even microcytic anaemia appeared to be due always

to a single deficiency even microcytic anaemia responded to crude liver extracts. Although liver extracts were more effective than refined, neither was as effective as in pernicious anaemia, and it is, therefore, considered that the deficiency present in the tropical anaemia is not identical with that of pernicious anaemia. Further nutritional macrocytic anaemia as seen in Uganda can be distinguished from pernicious anaemia in the stained film: the bone marrow is not megaloblastic in the strict sense of the term, and indeed the anaemia is often not macrocytic—it may be normocytic or macrocytic and it is usually associated with some degree of iron deficiency and a varying parasitic infection.

F. Murgstroyd

WATSON Janet with the technical assistance of Albert W. STRAHMAN & F. P. BILILLO. The Significance of the Pancyt of Sickle Cells in Newborn Negro Infants. *Amer J Med Sci* 1948 Apr., v 15 No. 4 419-23. [46 refs.]

The rarity of sickle cell disease in infancy is surprising in view of its frequency in later childhood, which suggests that the potentiality for sickling is incompletely developed at birth. Of 228 negro mothers 18 (8 per cent) showed sicklaemia, and in those affected the percentage of red cells sickling was usually 100 and exceeded 84 in every case. Of their 228 newborn infants, 19 (8.4 per cent) showed sicklaemia, and in the affected infants the maximum sickling varied from 0.5 to 29.5 per cent. of the red cells with a mean of 11 per cent. Sickling of the infants' red cells often required 48 hours to reach a maximum instead of the 4 hours which usually sufficed for the mothers' red cells. Presumably a lower oxygen tension is required to sickle infants' cells, and as there is a significant shift to the left of the oxygen dissociation curve of oxyhaemoglobin at birth which only gradually reaches adult values at the age of six weeks, the longer period necessary for sickling in the newborn may be due to a greater affinity of foetal haemoglobin for oxygen compared with the adult type of haemoglobin. This would not however account for the low percentage of sickled red cells in newborn infants since the maximum percentage of sickling could not be raised by use of a gas chamber method in which oxygen was excluded entirely from the system. Simple immaturity of the cells is not a sufficient explanation either because although normoblasts and reticulocytes sickle less readily than mature erythrocytes the blood of the infants contained no high percentage of immature cells. There is however evidence that human foetal haemoglobin differs chemically from adult haemoglobin probably in the chemical structure of the globin. It is suggested that foetal haemoglobin is unable to produce sickling and that the sickling trait and the percentage of red cells showing the sickling trait progressively increase as red cells containing the adult type of haemoglobin are produced. The foetal haemoglobin disappears at the age of about 4½ months and the life span of the erythrocytes is about 4 months, so that if adult haemoglobin began to develop at birth four months would lapse before it would entirely replace the foetal haemoglobin. One infant observed over such a period developed 60 per cent. sickling at 4½ months compared with only 6 per cent. sickling at birth. Normally an oxygen tension of 45 mm. Hg is the threshold for sickling, and obviously the lower oxygen tension that occurs after birth should cause complete sickling and thus be incompatible with life. That at birth erythrocytes of the pathological findings of sickle cell anaemia in topsies of newborn or stillborn infants. It is therefore that the foetal haemoglobin lacks the sickling property (adult haemoglobin prevents the automatic extension of sickle cell disease from dehydrated water and partially protect the infant during the first four months of life during which time the foetal haemoglobin gradually disappears from the blood.

VALENTINE, W N & NEEL, J V A Statistical Study of the Hematologic Variables in Subjects with Thalassaemia Minor *Amer J Med Sci* 1948, v 215, No 4, 456-60, 3 figs [13 refs]

Cooley's anaemia, an inherited haematological disorder of people of Mediterranean stock, may be severe, progressive and almost invariably fatal, or relatively mild, it is suggested that the terms thalassaemia major and thalassaemia minor be applied respectively to the two types. The major variety occurs in about 1 in 2,400, while the minor variety occurs in 1 in 25 births to persons of Southern Italian or Sicilian stock in Rochester, New York. The minor variety occurs in well-nourished persons with hypochromic microcytic erythrocytes, which are frequently oval or appear as target cells, basophilic stippling is common. Haemoglobin and haemocrit values are usually but not invariably low, and by comparison the total number of erythrocytes is disproportionately high. The erythrocytes show increased resistance to haemolysis by hypotonic saline. There may or may not be leucocytosis, reticulocytosis and elevated icterus index, or splenomegaly. In 82 persons with thalassaemia minor, there was an average deficiency of 2 to 3 gm of haemoglobin per 100 cc of blood, the defect being superimposed on the normal levels of haemoglobin for male and female so that the males showed higher haemoglobin values than did the females similarly affected. The tendency for persons with thalassaemia minor to have relatively elevated erythrocyte counts was confirmed, only 2 out of 58 of the adult patients having erythrocyte counts below 5 million per cmm, in 48.3 per cent of thalassaemic females and in 85.8 per cent of thalassaemic males the counts were above 5½ million per cmm, while 57 per cent of the males had counts above 6 million per cmm. The mean corpuscle volumes and mean corpuscular haemoglobin values were markedly below normal. The mean corpuscular haemoglobin concentrations were not so markedly lowered, showing that although the red cells are small in volume, each cell for its volume is only moderately deficient in haemoglobin. *F Murgatroyd*

VENOMS AND ANTIVENENES

CECCALDI, J & TRINQUIER, E Recherches sur la toxicité des glandes salivaires de divers Colubrides aglyphes et opisthoglyphes africains [Study of the Toxicity of the Salivary Glands of different African Aglyph and Opisthoglyph Colubrids] *C R Soc Biol* 1948, Apr, v 142 Nos 7/8, 440-41

The authors studied the toxicity of the salivary glands of 8 species of Aglypha and 8 of Opisthoglypha by injecting saline suspensions of the macerated glands into mice in successive dilutions. All the Aglypha except one killed less than 4 mice and that one killed 8. 5 of the 8 Opisthoglypha killed respectively 16, 32, 80, 320 and 5,120 mice. Two species of Opisthoglypha killed less than 4 mice and one killed 8.

The Aglypha studied are not likely to be harmful to man. On the other hand, certain of the Opisthoglypha investigated seem capable of causing fatal accidents in man. This applies especially to *Dipsadomorphus blandingii*, which killed 320 mice in the tests and *Elapops modestus* which killed 5,120.

TRIQUETIER, E. & CECALDI, J. Toxicité des glandes salivaires chez quelques Viperidés africains à leur naissance. [Toxicity of the Salivary Glands of some African Vipers at Birth.] *C. R. Soc. Biol.* 1948, Apr., v 14, Nos. 7/8 441

It is known that new-born venomous snakes have well-developed salivary glands and venom comparable with that of adults but few investigations are recorded on quantitative studies, particularly in African snakes.

The authors investigated this point in the new-born of two species *Buthus gabonica* and *Buthus masicornis*. Successive dilutions of saline emulsions of the glands were injected into mice.

In the case of *B. gabonica* emulsions from 2 glands were enough to kill 640 mice but not 1,280 the venoms were lethal for at least 11 kgm. of animal. Similar emulsions from new born *B. masicornis* killed only 4 mice its venom was thus far less toxic than that of *B. gabonica*.

These differences were maintained in adult life experiments showed that venom from a large adult specimen of *B. gabonica* was lethal to mice at the order of 485 kgm. of animal, while in the case of *B. masicornis* the figure was 110 kgm.

CONSTANT, Y. & GOUTIER, P. Sur les phénomènes d'arabisme provoqués par *Latrodectus mearnsi*. [Symptoms of Bites by *Latrodectus mearnsi*.] *Bull. Soc. Path. Exot.* 1948, v 41 Nos. 3 & 234-7

The specific name *mearnsi* was given to this spider because it is a *Madrascus*, word indicating red spots behind. Bites by it are generally dreaded by both indigenes and by Europeans. Detailed accounts of three cases are given: one patient was bitten on the inside of the left thigh, one on the right instep, and one on the back. The symptoms in the first and third were similar: pain at first local but soon extending widely over the body but greatest in the legs; no loss of reflexes, profuse sweating, retention of urine, albumin present in the small amount which may be passed and a little blood, an urticarial peripartous rash on the 3rd or 4th day, slight rise of temperature at first later falling below normal, and recovery in 5-8 days. In the second patient the early symptoms were the same, but signs of cardiac failure set in and in spite of all the remedies tried death occurred 27 hours after the induction of the bite. No work has yet been done on the venom of this spider and treatment at present is purely symptomatic, to ease the pain, check the sweats and combat the failing heart.

DERMATOLOGY AND FUNGUS DISEASES

CAHILL, F. W. The Effect of Hydrogen-Ion Concentration on the Yeastlike Phase of *Histioplasma capsulatum* (Darling). *J. Lab. Hyg. Assn. Wash.* 1948, June 4 v (3) No. 23 39-40, 16 [10 refs.]

The purpose of the author's experiments was to find liquid medium suitable for the propagation of *Histioplasma capsulatum* in its pure, smooth, yeast-like form. Five strains of the fungus were tested for growth on three different media over a wide range of pH at incubation temperatures of 25°C. and 37°C. (The fungus cannot vegetate in the yeast form at 25°C. on any medium.)

The following results refer to cultures inoculated at 37°C. On a glucose (1 per cent.) broth medium the yeast form showed a marked tendency to revert

to the mycelial form under all conditions of the test, so this medium was discarded as unsuitable. On beef-extract-broth the best results were obtained at the hydrogen-ion concentration of pH 7.3, but in the higher and lower pH ranges there was a slight but increasing tendency to develop rudimentary mycelium. "Difco" brain-heart-infusion-broth proved the most satisfactory medium, with optimal conditions in the pH range 7.4 to 7.5, but again in the higher and lower pH ranges there was a tendency towards reversion to the mycelial form, this was greater in the lower pH range, but in the higher range it was accompanied by retardation of the growth of the yeast form.

J T Duncan

RAWSON, A J, COLLINS, L H, Jr & GRANT, J L. **Histoplasmosis and Torulosis as Causes of Adrenal Insufficiency** *Amer J Med Sci* 1948, Apr., v 215, No 4, 363-71, 5 figs [25 refs]

A tabular analysis is given of eight previously published cases of histoplasmosis (*Histoplasma capsulatum*) in which necrosis of the adrenal glands induced symptoms of adrenal insufficiency, and eleven other cases of histoplasmosis and one of torulosis (*Cryptococcus [Torulosis] neoformans*) in which the adrenal glands were involved without symptoms of adrenal insufficiency, are noted. This is followed by detailed reports of the ninth case of adrenal insufficiency due to massive necrosis of the adrenals by *H. capsulatum*, and a case, claimed as the first, of torulosis characterized by adrenal insufficiency. The latter was only diagnosed as torulosis at post mortem examination. In both patients, who were women aged 62 and 41 years, respectively, excessive weakness was the first symptom.

Attention is drawn to the fact that in the cases of adrenal failure due to *H. capsulatum*, the ratio of 2 males to 1 female is the same as that noted in Adamson's disease from all causes although the age group (39 to 63) is somewhat higher than that for Adamson's disease (30 to 50).

G C Ainsworth

SMITH, C E, WHITING, E G, BAKER, E E, ROSENBERGER, H G, BEARD, R R & SAITO, Margaret T. **The Use of Coccidioidin** *Amer Rev Tuberculosis* 1948, Apr, v 57, No 4, 330-60, 2 figs [56 refs]

This detailed study of coccidioidin and its diagnostic use should be read in the original. After dealing with the relatively crude preparations of coccidioidin used in the earlier work on coccidioidomycosis, the authors recommend the method of preparation in common use in the United States at the present day. This consists in growing selected strains of *Coccidioides immitis* for 2 months at 22°C in a modification of the synthetic, liquid, asparagine medium devised for the production of tuberculin. The culture liquid is then filtered through a Seitz filter and the sterile filtrate, preserved with 1:10,000 merthiolate, constitutes the stock coccidioidin. As the asparagine medium does not cause dermal reactions, test control injections are not necessary.

The active principle of coccidioidin, which is mainly or entirely of polysaccharide nature although a small amount of apparently non-protein nitrogen is always present, is extremely stable and will withstand a temperature of 120°C in the autoclave for 10 minutes, or flowing steam for an hour. If sterile and undiluted it can be kept in cold storage for an indefinite time without loss of potency and in fact, a sample left at air temperature in a warm climate for nearly 9 years was found to be fully potent for the skin test. Even when diluted to 1:100, it can safely be kept in cold storage, but bacterial contamination may render it inert or may even cause it to give spurious positive reactions.

Coccidioidin should be standardized by intradermal tests on known human reactors, non reactors and equivocal reactors. The test dosage recommended is 0.1 ml. intradermally of a 1:1,000 dilution for active early cases, or down to 1:10,000 if erythema nodosum, indicating high sensitivity is present in the disseminated disease in which sensitivity may be very low or absent. A 1:10 dilution may be necessary and for epidemiological survey work a 1:100 dilution may be used on the average. The reaction is sufficiently specific for its purpose and it is of the delayed type like the tuberculin reaction. It is nearly always discernible at 4 hours, reaching its maximum at about 72 hours but it may develop earlier or later and, therefore interval readings should be taken. Dermal sensitivity to coccidioidin cannot be induced passively by injecting the serum of a reactor into the skin of a non-reactor nor does the skin become sensitized by the repeated injection of even strong doses of coccidioidin into the skin of a non-sensitive subject although he may become sensitive later from a natural infection. Dermal sensitivity usually appears a few weeks after infection, but its onset may be delayed. It may be of only transient duration, but it usually lasts for many years. J. T. DUNN

NABARRO J. D. N. Primary Pulmonary Coccidioidomycosis. Case of Laboratory Infection in England. *Lancet*. 1948, June 23, 962-4 2 figs. (28 L.)

See *Bulletin of Hygiene* 1948, v. 22, 688.

RUSO E. & GOMES R. P. Novas observações de esporotricose. [Fresh Observations on Sporotrichosis.] *Hospital Rio de Janeiro*. 1948 Feb. v. 33 No. 2, 15-22, 9 figs.

Four cases are briefly recorded: one a girl of 8 years, with a warty lesion of the right cheek; one, a girl of 17 years, with a lesion of the left hand between the thumb and forefinger; third, a boy of 12, with lesions of the left hand and forearm; the fourth, an adult woman with a small lesion on the ulnar side of the base of the right little finger and later two others near the cubital fossa.

The chief interest of the paper, however, is that all were diagnosed by isolation of *Sporotrichum schenckii* grown on Sabouraud dextrose medium, a blackish pigment. On transfer to ordinary agar pH 6.6 it grew well but white, with no pigment at all and continued to do so on this medium. When, however, it was retransferred to Sabouraud's medium again it again assumed the coloured growth. H. HAROLD SCOTT

HEAT STROKE AND ALLIED CONDITIONS

STEWART W. Effects of Heat with special reference to its Occurrence in British Troops in the Persian Gulf Area in 1941-42. *J. Roy. Army Med Corps* 1943, May v. 90 No. 5 178-93 3 figs. 18 L.

In the summer of 1947 there were 168 cases of heat stroke with 32 deaths and 1,933 cases of heat exhaustion with 13 deaths among the British troops in the Persian Gulf at a 14.9 per cent of the total British strength was affected. The author gives a brief description of these cases and considers them in relation to recent work on the physiology of man in the heat and on the pathological changes found in men suffering from the effects of heat.

The author distinguishes four types of heat effects: (1) Heat exhaustion; (2) Subacute effects of heat; (3) Heat cramps; and (4) Acute heat stroke. The

line of distinction between the first three is difficult to draw, but subacute effects, if untreated, may develop into heat stroke, which is acute hyperpyrexia

Immediate treatment is essential with controlled replacement of water and salt, and, for hyperpyrexia, active cooling. The importance of suitable clothing, adequate rest, proper acclimatization and a sufficient intake of salt and water in avoiding heat casualties is emphasized. Periodic medical examinations of all those serving in hot areas is advised.

[This paper would serve as a useful introductory review of the subject, but it adds nothing to our knowledge of heat effects. The author's classification of the different types of effects of heat is not universally accepted, 'it is the same as that given in the official memorandum reviewed in this *Bulletin*, 1944, v 41, 74.]

MISCELLANEOUS DISEASES

COUTINHO, A. Eosinofilia tropical [*Tropical Eosinophilla*] *Hospital Rio de Janeiro* 1948, Jan, v 33, No 1, 77-85 [25 refs]

The author records five cases which presented the symptoms of tropical eosinophilia—asthmatic attacks, eosinophilia ranging from 56 to 71 per cent in a leucocytosis from 12,000 to 26 500 per cmm. Unfortunately these records make confusion worse confounded rather than elucidate this vexed question. Each of the cases is given in detail, one disappeared and could not be followed up, the others cleared up under different forms of treatment. Two were suffering from amoebiasis and were treated with emetine, enterovioform and carbarsone, another, a medical man, seemed to be an ordinary case of bronchial asthma which cleared up with ascorbic acid and calcium. The only positive finding here was a strong reaction to tuberculin, 1 10,000. The remaining patient improved on penicillin and sulphadiazine, but still suffered with slight attacks of nocturnal asthma and was given an autogenous vaccine of *N. catarrhalis*, *Pneumococcus* and *H. influenzae* and improved markedly when abdominal pain elicited the fact that he had a duodenal ulcer. On the idea of a possible Löffler's syndrome he was given arsenicals and the dyspnoeic attacks disappeared completely though he still had some stertor. [An interesting series of cases, but leaving the subject as obscure as before.]

FERRO-LUZZI G. Studio sui fenomeni di malnutrizione in Eritrea. Nota II [*Malnutrition in Eritrea*] *Boll. Soc. Ital. di Med. e Igiene Trop.* (Sez. Eritrea) 1947, v 7, Nos 5/6, 483-94, 1 fig. English summary.

This article is an informative and interesting account of a disease known for many years (the author says "for centuries") among those consuming the seeds or flour made from the seeds of a plant known as "seberè". It grows on the upper levels and is abundantly cultivated and used fresh or cooked, alone or with other kinds of flour for making cakes (*chuccia*) which are eaten by all and sundry. It is cheap, easily cultivated, needs little water and is not liable to damage by acarides. Usually only a small proportion is used, mixed with other flour, but at times when other flour is scarce the proportion is higher. This happened after an invasion by locusts in 1946. If more than 50 per cent of the flour is used for making these cakes symptoms appear in 20-100 days according to the quantity eaten.

Seberè was identified as *Lathyrus sativus*, some samples are adulterated with *Vicia sativa*, but samples sent to the Agricultural Department of Eritrea were

not so adulterated. The symptoms were those of spastic paraparesis characteristic of lathyrism and affected males and females of all ages, but more particularly the poorer classes who consumed this flour in larger quantities. Details are given of six patients and an illustration of one of them showing the attitude and gait of typical spastic paraparesis. Five were males, aged 7, 8, 17, 25 and 33 years, and one woman aged 70. There was no disturbance of vision, no psychic symptoms, no change in the cerebro-spinal fluid. Very rare was any affection of the upper limbs or of the plantar reflexes. Vitaminosis did not seem to play any part primarily, but it may aggravate the basic lathyrism; the administration of vitamins had no curative effect. Prophylactic measures are obvious but attempts at cure have altogether failed.

PROTOZOOLOGY GENERAL

BUJLMEYER, J. On the Recovery of Protozoa and Eggs of some Species of Helminths in Human Faeces. *J. Parasitology* 1948, Apr. 34, 1-101, 7 [10 refs.] [See this *Bulletin* 1947 v 44 1101.]

SEAMAN, G. R. Penicillin as an Agent for Sterilization of Protozoan Cultures. *Science* 1947 Oct. 3 377.

The author concentrated *Colpoda macropoda* by centrifugation and washed the organisms three times with sterile Hahnert's solution (Phys. Zool. 1932, 5:491). A few drops of the washed concentrate were added to 3 per cent. sterile Disco proteose peptone solution containing 5,000 units of penicillin G. After 12 hours in the penicillin solution, the organisms were transferred through three successive washes of 3 per cent. proteose peptone. A drop containing the organisms and the fluid from the last wash was plated on agar in 8 tests; no bacterial growth was seen and the colpudae were apparently uninjured by 12 hours' exposure to this concentration of penicillin.

It seems that this method may be used to obtain sterile cultures of most protozoa but the survival time of each species of colpoda in given concentrations of penicillin must be ascertained separately. At the same time, even at lower concentrations are required. Preliminary tests suggest that *Paramecium caudatum* remain viable for 5 hours in a solution of 500 units of penicillin G, but is killed in 1-2 hours at the concentration of 500 units. It is added that the process does not require constant stirring. The number of organisms recovered and the number of transfers is reduced to a minimum.

TEDESCHI, G. G. An anti-toxic action of a pigment from *Leptotheca* [Antiprotazoal Action of a Pigment from *Leptotheca* 1, 2, 7]. *Riv. di Parasitol. e Zoon. 1948* Mar. 4, No. 1, 59. English summary (4 lines).

In the author's laboratory a strain of *Leptotheca* was isolated from culture contaminated by it. It was found to produce a pigment having very

definite action on certain protozoa. On further study a method of extraction of this pigment was devised. The mould was cultivated on a liquid Sabouraud's medium in a Roux flask at 30°C till it had developed fully. The growth was then removed very carefully to avoid damaging it and detaching the spores, and was then placed to dry at a temperature of 40°C. When completely dried it was extracted with chloroform in a Soxhlet apparatus till the extracting solvent came away colourless. When concentrated the solution had a deep yellowish-brown colour, it was allowed to cool and treated repeatedly with phosphate solution at pH 7.5 when it became yellow. The chloroform was then driven off and the product brought to pH 3 with HCl or H₂SO₄, a flocculent precipitate formed and on centrifuging a greenish-yellow product was obtained which was repeatedly washed with distilled water, brought up to pH 6, then dried, and NaOH cautiously added to obtain a clear liquid of an intense brown colour at pH 2.5.

Testing this, the author found that it had no action on *Bact. coli*, very little on *Staph. pyogenes aureus*. It was haemolytic but not if serum were present, in fact, haemolysis could be prevented by addition of serum. On protozoa the following results were observed. *Polytoma uvella* (a flagellate) was fixed at once, *Paramecium* was immobilized but not permanently, *Hartmanella hyalina*, a coprozoic amoeba, was immobilized with extended pseudopodia, *Giardia enterica* [*G. intestinalis*] moving in liquid faeces was immobilized and killed. *Trypanosoma lewisi* and *T. gambiense* in blood were rapidly immobilized. It was active on these also when injected into experimental animals, white rats and guinea-pigs, in a dose of 3 cc of the solution per 100 gm body weight, and apparently caused no systemic disturbance. *H. Harold Scott*

The English summary appended to the paper is as follows —

'The author reports the description of a peculiar organ present in the pretarsus of *Culex pipiens autogenicus*'

MACFIE, J. W. S. Some Species of *Culicoides* (Diptera, Ceratopogonidae) from the State of Chiapas, Mexico. *Ann Trop Med & Parasit* 1948, Apr, v 42, No 1, 67-87, 10 figs

The author has examined a portion of a large collection of Ceratopogonidae estimated to contain 20 000 specimens. Most of the material was collected by Dr A. Dampf from May to July, 1935, in Mexico.

The portion examined includes 3,335 specimens of *Culicoides* of which 97 per cent were *C. guttatus*. (It was in specimens of this species that Dr Dampf found developing filariae in 1936.) The remaining 3 per cent contained sixteen other species, ten of them are new and are described in this paper. A key is

given for the identification of some sixty species of *Culiseta* (females) likely to be found in the Caribbean area, including also species occurring in regions ranging from southern Mexico to Brazil.

H. S. LECHE

THEODOR O. Classification of the Old World Species of the Subfamily Phlebotominae (Diptera, Psychodidae). *Bull. Entom. Res.* 1948 May v 39 Pt. 1 83-115 15 figs. & 2 pls. [33 refs.]

The present paper is a valuable review of the systematics of the sand flies (*Phlebotomus*) of the Old World, written by an authority on the subject. These insects have not been monographed since the paper by LUNDAUSCH [this *Bulletin* 1921 v 18 196]. At that time 37 species and 8 varieties were known; the present author deals with 127 species and 34 varieties of which he has seen the greater part himself.

It might be said that some previous workers on the subject have tended to be "Phlebotomist" rather than Dipterists, for they have developed a terminology in connexion with sand flies alone with little regard for terms which are used for the Diptera generally. The present author takes account of comparative anatomy which will entail a few alterations in the use of technical terms. With regard to buccal cavity and pharynx he is conservative, basing his view on the work of SYNGRASS (*Principles of Insect Morphology* 1935, McGraw Hill New York) he does not accept "pharynx" and "oesophageal pump" terms put forward by JORLING [this *Bulletin* 1928 v 5 825] for certain structures in *Culiseta* which are plainly identical with those in *Phlebotomus*.

The earliest clear reference to these insects is that made by Scopoli in 1766. The growth of knowledge since that time and the earlier system of classification are here reviewed and on a basis of this earlier work much of which is still valuable the author puts forward his own views. He classes *Phlebotomus* and the other blood-sucking genera immediately related to it as a sub-family the Phlebotominae of the family Psychodidae. In doing this he rejects a proposal made by ADLER and himself [this *Bulletin* 1930 v 7 189] to create a separate family for the blood-sucking forms and we are glad to see that he has done so. The other three sub-families of the Psychodidae contain no biting forms (the record of biting by *Pericoma lutescens* Taylor 1915 being rejected).

The Phlebotominae are divided into four genera: *Phlebotomus*, *Sergentomyia*, *Lutzomyia* and *Brumptomyia*. Of these the last two are exclusively American, the first two with which this paper is concerned are characterized on the following points among others—

Phlebotomus: Rondani, 1843.—Species without armature in buccal cavity. Pharyngeal armature generally similar in male and female. Hair on dorsum of abdomen mostly in erect tufts. Spermatheca completely or incompletely segmented. This genus contains nearly all the species which feed on mammals and all those which are implicated in the transmission of human infections.

Sergentomyia Franca and Parrot 1920.—Species with a buccal armature marked sexual dimorphism in buccal and pharyngeal armature. Spermatheca generally smooth or crinkled lobes or capsule, incompletely segmented in a few forms. Only a few members of the genus are known to bite man (*S. aethiops africana* and *S. h. h.*) it is known that some feed on bird and reptiles.

The author defines a number of sub-genera some of which are new both in *Phlebotomus* and *Sergentomyia* naming the type species of each and providing a key to the sub-genera. The paper concludes with a list of all the Old World

species and authorities with a few words on the geographical distribution of each. A number of names are sunk as synonyms for reasons not given here. The paper is concluded with a list of works "concerned with classification", and with two excellent plates of photomicrographs showing characteristic details of structure. P A Buxton

DRAN, G M Armillifer Armillatus A Note on Three Cases of Calcification
of the Cysts in Man Brit J Radiol 1948, July, v 21, No 247, 342-5,
6 figs [17 refs]

The diagnosis of porocephalosis in the living subject is rare, but cases have been reported from time to time, most of these have been concerned with calcified nymphs of *Armillifer armillatus*, which probably do not produce symptoms as a rule, but cases in which pathological effects were noted have been recorded [this Bulletin, 1947, v 44, 136, 626].

The present author, from the Royal Liverpool United Hospital, discusses this form of infestation and refers briefly to the literature. He then records three cases in which multiple calcified nymphs were demonstrated radiographically in natives of West Africa.

The first patient was complaining of pain in the back and osteoarthritic changes were found in the spine. Very many calcified nymphs of *A. armillatus* were demonstrated in the abdominal cavity and there were one or two in the upper zone of the right lung. It is not considered that the symptoms were due to the presence of the nymphs. The second patient had suffered from a cough and pain in the chest for a month. radiography showed numerous calcified nymphs over both lung fields. The third case had similar symptoms and radiological appearances.

All these findings are illustrated with X-ray photographs in the text. When the nymphs are seen *en face* they are unlike any other calcification, but when seen "end on" over a muscle area, they might easily be confused with the cysts of cysticercosis. Atypical forms might be confused with calcified glands, calculi and the like, but calcified tuberculous foci are not common in natives of West Africa.

The author refers to the paucity of information regarding such calcified nymphs in the standard text books and he stresses the need for keeping the condition and its features in mind. Once it has been seen, it will not readily be forgotten and after the first of his cases had been recognized there was no difficulty in identifying the others.

The living larvae may be another cause for transient pneumonias and haemoptyses. The author suggests that a skin test might be developed to detect the living parasite. It is likely that with an extension of radiographic services in the tropics, more cases will come to light.

The author's present three cases bring the total record of radiographically demonstrated cases up to five. H J O'D Burke-Gaffney

HAJOSIKOLAU J & BUSHNELL, J. R. Toxicity of Limewash containing DDT or "Gammexane" to Mosquitoes (*Aedes aegypti* L.) *Bull. Entom. Res.* 1948 May v 39 Pt. 1 179-83 1 fig

In many rural malarious districts, the dwellings have mud or plaster walls, brightened by an annual coat of whitewash. The object of the tests described was to investigate the feasibility of incorporating DDT or *gamma* BHC in limewash to give a residual action against mosquito adults.

The tests were done in one-foot-cube cages, each with a screen and window in the front to introduce and watch the insects. The walls, which were removable, were made of pieces of Essex board one foot square. This is an absorbent material offering difficulties to applying residual films of insecticides. The Essex boards could be treated in various ways and applied to the cage framework for test. Mosquitoes were introduced for various periods of exposure and then removed to a clean cage; the mortality was determined after twenty-four hours. During the exposure mosquitoes were free to fly or to settle on the untreated portions of the cage, which comprised about thirty per cent. of the total internal surface. *Aedes aegypti* were used as the test insects on account of the ease in producing large numbers in the laboratory throughout the year.

The experiments were made with applications to the walls of a DDT wettable powder mixed with lime to give a whitewall coating, and this treatment was compared with DDT applied in kerosene solution at the same rate (100 mgm/sq. ft.). In the whitewash application an eventual mortality of 85-90 per cent was obtained after an exposure of two hours; the result with the kerosene solution application were inferior. Equally high kills were obtained with much lower rates of *gamma* BHC (8 mgm/sq. ft.) applied in a stable powder mixed with limewash.

Repeated tests made at intervals indicated that both the DDT and *gamma* BHC whitewash applications remained highly effective up to about 6-8 weeks under temperate conditions. A higher rate of *gamma* BHC (140 mgm/sq. ft.) gave a complete kill with a one-hour exposure after twenty-two weeks interval. The DDT treatment was not tested after eight weeks until seven months, at which point it showed signs of deterioration. J. R. B.

Experience is necessary to overcome the interruption of vision due to respiratory movements, and to interpret the observations on circulatory changes. The author suggests that the flow through the splenic pulp of mice is by tortuous channels, constant in position, and ramifying between the splenic cells. There is no evidence for a closed circulation.

All observations may represent the normal modified by anaesthesia, exposure, disturbance of surface pressure, temperature etc. The illumination used is insufficient for the photography of moving tissues. *E T Renbourn*

REPORTS, SURVEYS AND MISCELLANEOUS PAPERS

WORTH, H I. *The Age Question among Asiatic Girls in Malayan Courts of Law*
Med J Malaya 1947, June, v 1, No 4, 252-71

European standards on height, weight, centres of ossification and date of onset of puberty are not applicable to Asiatic girls in Malaya. "Asiatics" could not be grouped together, racial groups showed differences, especially the three main groups—Chinese, Indians and Malays.

Nine tables are furnished showing the average and maximum and minimum heights and weights of the four main groups examined, as well as of some of the minor groups, arranged according to ages from 5 years to 19 years. The conclusion is drawn that the European standard of height and weight is higher than that of any of the Asiatic races in Malaya, a greater difference is noted in the weight than in the height and there is a much greater range in the weight of Asiatics but a smaller range in the height.

Onset of menstruation tended to be earlier in the local Asiatic groups than in Europeans.

The date of eruption of permanent teeth appeared to be earlier among Asiatic races. No deciduous teeth were found at the age of 12-13 years, the lower second molar was seen in all those examined at that age and the whole lower set was present, excluding the third molar. Earlier eruption of the canine teeth was also noticeable.

Details should be consulted in the original by all those interested in medico-legal work in tropical countries. *P A Clearkin*

BOOK REVIEW

SERGEANT, Edmond & SERGEANT, Etienne. *Histoire d'un marais algérien* [The History of an Algerian Marsh]. 293 pp, 18 pls, 3 folding maps & numerous text figs. 1947. Alger. Institut Pasteur d'Algérie.

In 1911 the authors with Dr E Roux were motoring along the Mitidja Plain. They passed a derelict farm that had had a tragic history—a promising enterprise that had been brought to disaster by malaria. That experience prompted Dr Roux's suggestion that the Pasteur Institute of Algiers should seek out some similar place, not too far from the Institute, that malaria had made uninhabitable. It should be reclaimed, freed from its malaria and brought back into cultivation, as a practical demonstration of what recently acquired

knowledge of the epidemiology of malaria might accomplish. Dr Roux promised to provide the funds necessary for the acquisition of such a property. The 1914-18 war intervened and it was only in 1927 that the Pasteur Institute obtained possession of land in every way suitable for the purpose of the experiment. 700 hectares of marshland in the Moudja Plain, 25 km. south west of Algiers the *Marais des Ouled Mendil*. Malaria had made it uninhabitable. *peroplasmosis* had prohibited its use as a grazing ground.

The *Il storie d'un Marais Algérien* a charming volume describes that marshy waste as it was, and gives a graphic account of the measures that step by step succeeded in transforming it into a malaria free flourishing agricultural property. Today it is a very valuable adjunct to the Pasteur Institute of Algiers. Colmatage, drainage, road making, tree planting, farm building, agriculture well sinking were all systematically taken in hand. Forty six Europeans have dwelt in that once malaria infested spot, the average length of stay being four years. All remained free from malaria infection. European cattle vaccinated against *peroplasmosis*, thrive.

This great achievement is very worthily commemorated in this lyrical volume enriched with delightful illustrations and innumerable apt quotations. The history is much more than a record of achievement. It provides interesting information about Algerian history, ancient and modern, archaeology, geology, fauna, flora, man's tribute to malaria, the history of malaria research and antimalarial methods. Its perusal is a pleasure to which the wealth of apt quotations from the classics contributes much.

VORMAN WHITE

We record with the greatest regret the death of
Lt-Colonel W. F. HARVEY and Dr C. M. WENYON.

Lt-Colonel Harvey who died in Edinburgh on
September 11 1948 contributed abstracts of bacterio-
logical paper to the *Tropical Disease Bulletin* from
1923 onward and was later sectional editor for cholera
and plague prior to the time of his death.

Dr Wenyon died in London on October 4 1948.
He was editor of the *Kala Azar Bulletin* in 1911 and
subsequently for the last 16 years was sectional edit-
or of the *Tropical Diseases Bulletin* for leishmaniasis and
trypanosomiasis.

SUMMARY OF RECENT ABSTRACTS*

IX LEPROSY

Epidemiology Transmission

In the *British Medical Journal* (p 719) is an account of 6 cases of leprosy which occurred in Britain in persons returned from the Far East. The importance of bearing leprosy in mind in cases of resistant skin lesions is emphasized. In a survey of 42,811 school children in British Guiana WHARTON (p 720) found 94 cases of leprosy, 91 of which were early nerve cases. FLOCH and DE LAJUDIE (p 322) estimate that the incidence of leprosy in French Guiana is about 65 per 1,000, with the highest rates at the age of 6-10 years. Family infections and school infections are common. The same authors (p 589) give a detailed account of the progress of a considerable number of leprosy patients in French Guiana. They record incubation periods as short as 9 and 15 months in two infants. The proportion of leprosy patients showing lepromatous or mixed lesions is higher in Europeans, Arabs and the penal classes than in the Creole population.

In Cuba a census revealed 2,166 persons suffering from leprosy in 1946. OTEIZA SETIEN *et al* (pp 95, 589) show that the incidence of ambulatory cases varied from 0.163 to 0.6 per 1,000 in different parts of the country, and that the rate in intimate contacts was 33.4 per 1,000. There are 2 special hospitals. Infants born in hospital to diseased parents are separated from them at birth, to be brought up away from infection. IBARRA PÉREZ and GONZÁLEZ PRENDES (p 430) show that the incidence of leprosy in Cuba is in the ratio of 1.52 males to 1 female. In Argentina, FEDERICO GUILLOR and OSVALDO CURCI (p 591) found the proportion of 1.82 male to 1 female leprosy patient, and the predominance of males is generally noted in other countries. They discuss leprosy in women and its relation to pregnancy.

DHARMENDRA and SEN (p 324) give an account of familial and contact spread of leprosy in relation to a family in Calcutta.

MOISER (pp 321-725) is unable to accept the view that long-continued close contact is necessary for the transmission of leprosy, and puts forward once more his opinion that cockroaches are important in transmission. MUÑOZ RIVAS (p 1071) again discusses the possibility that leprosy may be transmitted by fleas. He shows that acid-fast organisms are often present in fleas and their

*The information from which this series of summaries has been compiled is given in the abstracts which have appeared in the *Tropical Diseases Bulletin*, 1947, v 44. References to the abstracts are given under the names of the authors quoted and the pages on which the abstracts are printed.

larvae in the dwellings of leprosy patients but not (in his experience) in the dwellings of healthy people. Inoculation of triturated fleas which had fed on leprosy patients into monkeys did not give clear-cut evidence. FLOOM and DE LAJUDIE (p. 774) have cultivated acid-fast bacteria from triatomid bugs which had fed on lepromatous thons and from mosquitoes caught in leprosy wards. They do not claim that these were leprosy bacilli.

Etiology

COCHRANE, MEXON and PAXDIT (p. 322) have repeatedly injected splenectomized monkeys with material from human leprosy patients. Some of the animals were also fed on *Colocasia esculenta* (which has been thought to predispose to the disease in man) and some were given preliminary injections of Indian ink. Although no dissemination was observed all the animals except those which received the Indian ink tended to develop strongly positive lepromin reactions after the third injection. COCHRANE and RAMANUJAN (p. 327) sum up the results of attempts to infect 38 monkeys with human leprosy material, which were made in the course of 6 years' work. They conclude that a positive lepromin reaction can be obtained only after a primary focus has been established and that *Mycobacterium leprae* cannot parasitize the reticulo-endothelial system unless it multiplies in the corium of the skin and can only develop if the R E system is intact. In tuberculoid leprosy the formation of epithelioid foci anchors the bacilli and prevents their dissemination throughout the R E system. But the authors have not been able to produce disseminated leprosy in the monkeys.

HAWKS (p. 323) gives the results of attempts to cultivate leprosy bacilli in small cubes of leprosy tissue placed in various fluid culture media or on solid media. He used a careful method to assess any increase in the number of bacilli but there was no evidence of multiplication in any experiment. He (p. 771) has carried out tissue-culture experiments with lepromatous tissue and although there was growth of fibroblasts other cells (containing the bacilli) died and there was no evidence of any growth of the bacilli themselves. The same author (p. 722) continued this kind of work, but with tissue from macular and tuberculoid lesions. The advancing border of the tuberculoid tissue in culture created a stronger impression of viable leprosy bacilli than any other form of leprosy but this was not maintained as the tissue cells proliferated. Fibroblasts from these resistant forms of leprosy rapidly ingested and destroyed bacilli with which they had been infected.

HAWKS (p. 722) continued this work by injecting carbon particles into the explanted tissue before culture. He observed that the fate of the bacilli was similar to that of the accompanying carbon particles except that the bacilli were less durable. By doubling the carbon dioxide pressure or by increasing the rate of growth of fibroblasts, the rate of disappearance of the bacilli was increased, and the distribution of leprosy lesions in the body is probably influenced by the same conditions as those which affect the fate of bacilli in cultivated fibroblasts. Internal organs have more ill-effects, greater incidence of mitotic cells, more active metabolism and lower pH than cells of the periphery. In work on rat leprosy he (p. 723) has shown that the injection of carbon particles does not influence the dispersal of leprosy bacilli and is of good control in experiments on multiplication of organisms. He (p. 723) thinks that the turbidity of plasma surrounding tissue cultures of lepromatous material is not due to increase of the numbers of leprosy bacilli as some investigators have thought but to calcification of the plasma. There is no evidence of multiplication of the bacilli.

The same author (p. 774) infected chick embryos and chick tissue cultures with bacilli from lepromatous nodules but there was no sign of proliferation of the bacilli in any of the experiments.

Diagnosis Tests

DE SOUZA-ARAUJO (p 1072) describes his method of clamping skin until it is ischaemic, and then puncturing it to obtain lymph for staining in the search for leprosy bacilli. A method for staining leprosy bacilli with Nachtblau (as for tubercle bacilli) is described by HALLBERG (p 591). It is particularly useful for sections. A method for staining the rounded thickenings sometimes seen in leprosy bacilli is described by DE OLIVEIRA CASTRO (p 1072). It is based on the Cooper modification of the Ziehl-Neelsen method. FITE *et al* (p 1008) describe a satisfactory method of staining leprosy bacilli in paraffin sections, using the stain Sudan black B for staining lipid material, that true leprosy bacilli do not contain intracellular material which is stained in this way, but that tubercle bacilli, and acid-fast organisms which have been cultivated from leprosy material, do. This supports the view that these cultivated organisms are not true leprosy bacilli, but are saprophytic.

As a result of a large number of examinations made of recruits in India, McDONALD (p 592) shows that examination of sections of suspected skin lesions can be very helpful in diagnosis. In 80 positive specimens only 1 was lepromatous, the rest were tuberculoid, with only scanty bacilli, but with the typical lesions and epithelioid-cell and round-cell infiltrations, and a few giant cells. Differentiation from skin tuberculosis is not easy and requires expert interpretation of the sections and of the clinical condition, there is no caseation in the leprosy sections and there may be peripheral neuritis with round-cell reaction.

Three types of lepromin are used by IGNACIO CHALA and LLERAS RESTREPO (p 823): whole lepromin (which gives a late reaction in tuberculoid leprosy, and sometimes an early reaction), filtered lepromin, and bacillary lepromin. The last is the most active and is recommended for routine work, strongly positive early reactions are given with filtered and anaesthetic nerve leprosy. The culoid leprosy but not in simple macular or tuberculoid leprosy, The preparation of these lepromins is described.

TISSEUIL (p 325) thinks that the lepromin reaction in tuberculoid leprosy, though positive in both diseased and healthy skin, is not specific, because reactions are also produced by injection of other acid-fast bacilli, and because lepromin sometimes gives positive results in healthy persons. The negative reaction in lepromatous disease is due to the fact that all the tissues, even those apparently healthy, contain the bacilli, and this negative result is specific because other acid-fast organisms give positive results.

GARCIA MIRANDA (p 431) states that in non-lepromatous persons, infection with *Mycobacterium tuberculosis* often provokes sensitivity to lepromin as well as to tuberculin. In leprosy patients, however, reactions to these two substances give discordant results. The lepromin test is a gauge of the body's defensive mechanism, and a negative result indicates absence of resistance [see TISSEUIL above]. GINÉS and POLETTI (p 528) similarly state that positive reactors to tuberculin are also positive to lepromin [see also this *Bulletin*, 1943, v 40, 247], and they show that inoculation of BCG may induce a state of reactivity to lepromin, and, perhaps, of resistance to leprosy.

CARBONELL and CONTRERAS DUEÑAS (p 592) compare the histamine skin test, in leprosy, with a test in which a substance (Priscol) is used which acts on the small arteries and arterioles rather than on the capillaries.

Clinical Findings

The classification of leprosy is discussed by MUIR (p 1073) who recognizes the two characteristic forms, lepromatous and tuberculoid, and the characteristic form which may remain so or which may progress to one of others, or be a stage in transition of one of the characteristic forms to

other or a stage on the way to recovery. Secondary classifications deal with clinical and topographical features, bacteriological findings and the lepromin test.

DAVY (p. 323) holds that in macular leprosy there is a wide range of lesions which shade into each other from the mildest of localized tuberculous lesions to innumerable poorly-defined macules of lepromatous type without effective localisation. The lepromin test is positive in the mild forms and shades to negative in the severe forms. There seems to be an allergic mechanism in all macular forms, which may appear suddenly.

COCHRANE (p. 1073) thinks that the corium of the skin is the site of active development of leprosy bacilli, and is the area of strategic importance in leprosy. The bacilli in the reticulo-endothelial system are mainly saprophytic. In India many cases of child leprosy are benign and non-progressive and practical consideration need only be given to simple neural leprosy and pre-lepromatous lesions, the latter comprising 5-10 per cent. of all child cases and developing in families in which there is the closest contact with infective patients. The benign cases in children do not require prolonged treatment.

ERMAKOVA (p. 726) shows that there may be injury to the nerves at the root of the tongue in lepromatous leprosy, but that only the sensory nerves are involved.

PARGO-CASTELLO *et al.* (p. 1074) state that nerve involvement occurs in lepromatous and tuberculous leprosy but differs in type in that in the former there is cellular infiltration with masses of bacilli, and in the latter there are thick infiltrations of lymphocytes, epithelioid cells and giant cells, but few bacilli, and caseation sometimes occurs. They therefore think that the so-called neural leprosy belongs to the tuberculous type. This view is not accepted by some workers.

TISSEUT (p. 726) describes the essential characters of tuberculous leprosy which should not be classified under nerve leprosy.

IGNACIO CHALA (p. 430) has described in detail the skin lesions of tuberculous leprosy. The account of this work cannot well be abstracted further and the description of the various forms seen should be sought in the original. He makes the point that the lepromin test is positive and that tuberculous leprosy is not infective and is therefore not a menace to the public health.

DHARMENDRA and SAXENA (p. 324) have studied the course of leprosy in 748 cases observed for 10 years in India. About one-quarter were lepromatous. Definite improvement or complete subsidence occurred in over 40 per cent. of the cases of nerve leprosy.

RADDA (p. 324) describes the progress of a number of untreated cases of early nerve leprosy. Most remained unchanged during several years, but a few improved and more deteriorated. Treatment with Calococa and sodium glycocholate was useful in a group of patients with similar lesions.

BRUNAD (p. 214) has investigated the blood glutathione in leprosy as an aid to the determination of the state of the oxidation-reduction processes in the patient, and hence of the extent of compensation of the leprosy process.

A description of the eye diseases seen in leprosy is given by MASSARD (p. 213).

Alopecia is not a rare complication of leprosy. It occurred in 86 per cent. of cases in the United States (FACET, p. 593).

MOSE (p. 1074) points out that the lepra reaction is an allergic phenomenon, and therefore presumably is due to a substance allied to histamine. He has tried benadryl, a synthetic anti-histamine substance with considerable success in the treatment of these reactions. POUET and ROSS (p. 593) have observed a transient red nodules resembling those of erythema nodosum, in the course of lepra reactions. These are most frequent in lepromatous leprosy. In a

number of cases a definite increase was found in the fasting blood sugar level, and there was evidence of increase of bile pigments in the urine during the reactions. The hyperglycaemia is probably related to the metabolic function of the liver. Treatment of cases of lepra reaction with insulin produced clinical improvement.

Treatment

MUIR (p 824) discusses the treatment of leprosy with the sulphone preparations, quoting his own previously published work and that of the Carville team. The drugs cost £6 per patient per annum [but at Carville the saving in dressings more than compensates for the cost of the drugs, see p 594].

FAGET and his colleagues at Carville (p 594) have issued a report summing up their experience of promin treatment in 177 cases for periods of 1-5 years. The usual course is now to give the drug intravenously 6 days each week for 2 weeks, followed by a rest of 1 week, this cycle is repeated, to give about 207 injections each year. It was necessary to stop treatment in less than 5 per cent because of untoward reactions. This treatment results in improvement in all major chronic manifestations, with bacteriological and histological improvement. MOM (p 594) gives the same doses of promin as are the rule at Carville (2 to 5 gm intravenously each day) but does not allow the same rest periods. His results have been good and have varied with the dosage and length of treatment. He also gives intravenous injections of ascorbic acid each day. He thinks that the use of chaulmoogra as well as promin is an advantage. PEYRI (p 1075) discusses the incidence of leprosy in a province of Mexico. He has treated 30 patients (16 lepromatous, 4 tuberculoid, 10 uncharacteristic) with promin, 2 gm intravenously each day for 6 days each week, with an interval of 15 days every two months. Improvement was seen in all after 200-300 gm had been given. WHARTON (p 326) observed considerable improvement in 7 lepromatous cases treated with intravenous promin.

MUIR (p 327) in England gives diasone by the mouth in a dose of 2.0 gm on each of 3 days each week for 3 weeks, with an interval of 1 week before the course is resumed. This is repeated time after time, and the dose may be pushed to 12 gm a week for 3 weeks each month if there are no reactions. Slight anaemia is treated with iron, liver and yeast. In this way he obtained favourable results in lepromatous leprosy, which had not been possible with chaulmoogra alone. FERNANDEZ and CARBONI (p 595) have had considerable success with diasone given by mouth in tablets containing one-third of a gramme each. The daily dose best tolerated is 2 gm for 8 weeks, followed by a rest of 3-4 weeks, and repeated. Intolerance may be noted after 2 weeks, but usually disappears if the drug is temporarily stopped, and there may be methaemoglobinaemia and anaemia which usually responds to anti-anaemia treatment. In lepromatous leprosy there is often marked improvement, with softening of the nodules and reduction in size.

FAGET, POGGE and JOHANSEN (p 326) record some considerable benefit in 7 patients with advanced lepromata treated for 1 year with promizole. The same authors (p 326) show that in 104 patients treated with diasone by mouth, and observed up to 2½ years, about one-quarter became bacteriologically negative and two-thirds showed improvement. It was necessary to discontinue treatment in a quarter of the patients, for various reasons, but in the rest the drug was well tolerated. The daily dose was gradually increased from 0.33 gm to 1.0 gm for adults.

FAGET (p 727) sums up his experiences with promin, diasone and promizole, the results of which have been very similar. The active principle of them all is apparently the diamino-diphenyl sulphone. Improvement was noted in almost all cases within 3 years, often in a much shorter period.

In an account of the work done under most difficult conditions at the large leprosy hospital in Malaya during the years of Japanese occupation RYU (p. 720) remarks that the lack of Hydnocarpus oil convinced him of its value. HEATHCOTT *et al.* (p. 777) discuss the methods of treatment (largely with neutralized chaulmoogra oils) and prevention (agricultural colonies for infective patients) used in the French colonies. BAKMAN (p. 908) notes the chaulmoogra oil irritates the stomach but he has given it in dogs and in man by duodenal tube and has satisfied himself that it is effectively absorbed.

Penicillin is apparently useless in leprosy (FIGUEROA and DEAR, *Panjo*, p. 214).

REESTIERMA (p. 728) states that electrophoretic analysis of his anti-leprosy serum shows that it contains more gamma globulin than normal serum and this he thinks is due to the presence of antibodies. The serum was prepared against an acid-fast bacillus cultivated from a patient with leprosy and regarded by the author as the cause of the disease (though many other leprologists would probably not accept it).

Improvement was observed in a number of cases of nerve leprosy treated by FIGUEROA and DEAR (p. 14) with intravenous methylene blue.

Good results in the treatment of leprosy ulcers were achieved by LANGSTON (p. 596) who used Tisacul's method of intramuscular injections of acetylcholine hydrochloride.

MOSE and BERNAL (p. 596) have used a weak solution of tyrothricin as a preparation for leprosy ulcers, with great success. 14 of 115 healed though they had resisted other treatments.

Control

MACKAY (p. 720) shows that at the Makete leprosy settlement in Tanganyika Territory there are about 1,500 inmates. Each patient has not less than 5 acres of land and can therefore become self supporting. Admission is voluntary and there is rarely need to separate husbands and wives because conjugal infection is rare. The incidence of leprosy in the children is also surprisingly low. In Central Africa only 5-10 per cent. of cases are lepromatous.

AUSTIN (p. 723) defends the system of compulsory segregation of leprosy patients in the scattered islands of Fiji where a voluntary system would not enable earlier cases to be found and treated. ROBERTS agrees that it is evidently a procedure suitable to those conditions, but condemns for Asia and Africa where the bulk of cases occur the indiscriminate compulsory isolation of all types of leprosy including the large numbers of non-infective nerve cases.

The problem of home isolation of leprosy patients in the Philippines is discussed in the *International Journal of Leprosy* (p. 377). Under the existing law only bacteriologically positive patients are isolated in institutions; negative patients are placed on parole. In the opinion of some of the members of the staff of the public health department home isolation is likely to fail and it would be unwise to relax the regulation in so highly endemic an area as the Philippines.

FUGET (p. 588) contributes a history of the National Leprosarium, Carville, U.S.A., where much work on treatment with primum and diasone has recently been done. In 51 years only one attendant has developed the disease.

CHALA (p. 597) describes the leprosy institutions of Columbia, where there are 3 large leproseries and 11 dispensaries.

Charles F. W. Smith

RABIES

REMLINGER, P & BAILLY, J La rage et le traitement antirabique pendant
ces vingt dernières années [Rabies and Anti-Rabies Treatment during
the Last Twenty Years] Biol Méd 1948, June-July-Aug, v 37,
Nos 6-7-8, 101-28 [247 refs]

In this exceedingly informative article the authors review the most important work published on rabies and on its specific treatment during the past 20 years. The following paragraphs summarize the points on which emphasis is laid.

The causal agent of rabies is a virulent substance of a protein nature. Endowed with powers of assimilation, it is capable of cultivation, particularly on the chorio-allantoic membrane of the chick embryo.

The Viverridae (civet family) in South Africa, Desmodidae (vampire bats) in Paraguay, Argentine and British West Indies, and skunks in the United States have to be added to the list of animals that transmit the infection in nature.

In West Africa, Equatorial Africa and in tropical countries generally, rabies and rabies virus behave exactly as in temperate regions.

The rabies virus occurs not only in the nervous system and salivary glands but also, owing to its central and peripheral nervous distribution, in almost every organ. It has been demonstrated in the suprarenals, spleen, liver, kidney, lung, testicle, Harder's gland, retina, choroid, vitreous body and crystalline lens, but not in the aqueous humour.

The Swiss mouse (preferably) and the white mouse are, in the opinion of many, animals of choice for experimental work on rabies. The former, ten times more susceptible to rabies virus than the rabbit or guinea-pig, is incomparable for assessment of the immunizing power of different anti-rabies vaccines (WEBSTER).

The "singleness" of street virus contrasts with the "plurality" of fixed virus—a virus "fixed" only in name. Fixed viruses differ among themselves more than street viruses, on repeated "passage" the former become more and more sensitive to the action of desiccation and of glycerin, less and less to that of dilution and of ether. Anti-rabies institutes should have subjected to periodic control the strains of fixed virus used in the preparation of their vaccines. Desiccation does not attenuate, it preserves the rabies virus. Attenuation of the virus in cords suspended in Pasteur flasks is achieved by proteolysis.

In almost every country the classical method of Pasteur and the dilution method of Hognes have been replaced by the use of etherized and, especially, phenolized vaccines, which retain their immunizing properties for months, can be despatched to places far from their place of manufacture and with which immunization can be effected in hospitals, dispensaries or even in the houses of the physician or of the bitten person.

Anti-rabies serum has failed in practice to fulfil the hopes to which it originally gave rise.

By reason perhaps, of the period of "neurotropism", through which we are now passing, the number of paralytic accidents complicating anti-rabies treatment is on the increase. In this connexion it is important to distinguish between "*rage de laboratoire*", where the virus used in treatment is recovered on autopsy, and the rightly termed "paralytic accidents" which, though usually less serious, are much more frequent.

Failures of treatment should not be concealed any more than the neuro-paralytic accidents of treatment. Often they result from an inadequate amount of vaccine employed. Blame must be laid not on Pasteurian treatment

MALARIA

WORLD HEALTH ORGANIZATION. INTERIM COMMISSION. Expert Committee on Malaria. Report of Second Session. Washington, D.C. May 18-25, 1948. 50 mimeographed pp. [W.H.O. IC/205. W.H.O. IC/Mal 25 8 June 1948.]

The report of this session of the W.H.O. Expert Committee on Malaria is important as would be expected. The members were GABALDON COVELL, RUSSELL, VAUGHN VISWANATHAN and PAMPONA assisted by AFRIDI FIELD Bagster WILSON AYKROYD ALVARADO ANTONES VARGAS CONTRAY HUFF SOFER and STAGE.

The report is divided into 10 sections, the first of which is an introduction and the second a very brief statement on world needs. Section 3 deals with W.H.O. malaria policy which is to assist governments to accomplish effective malaria control through W.H.O. regional organizations. It is concerned with programmes and machinery for control training the spreading of knowledge the development of uniform procedure and nomenclature and the promotion of measures to protect countries against the introduction of anophelines from the outside.

Examples are given of different existing antimalarial organizations such as those established in India and certain South American countries the emphasis being on elasticity. Training involves instruction of three grades of staff—directive professional staff, assistant professional staff and subordinate personnel—and it includes the means for making available to them the latest information from all over the world. Individual experts and operational demonstration teams should primarily demonstrate the use of residual insecticide spraying as a method of malaria control. Three teams should be formed as early as possible to be allocated, on request to Central Africa, South-East Asia and Tropical America.

The general public must be educated but the most effective propaganda is successful demonstration of practical malaria control.

In section 4 on Agriculture and Malaria there is a provisional memorandum prepared by the FAO in which are discussed such matters as the effects on agricultural production of ill health due to malaria and the possibility that malaria may be introduced into an area as a result of change of human or natural agencies for instance irrigation (possibility which may also apply to schistosomiasis).

Section 5 is devoted to the use of insecticides of which DDT is the most satisfactory. Benzene hexachloride has a shorter residual action and a disagreeable odour. DDD and TDE (1 trichloro-dibenzylethane) are useful larvicides where the safety of fish needs consideration. chlordane and chlorinated camphene do not possess as long an effective residual action as DDT. combinations of pyrethrum with piperidine compounds increase the effectiveness of the pyrethrum, but need more investigation. parathion is toxic for warm-blooded animals.

The committee expresses the opinion that there is definite and overwhelming evidence that modern insecticides properly applied can be relied upon to produce a significant reduction in malaria morbidity though doubt has been expressed in Africa as to the efficacy of DDT in *Anopheles gambiae* and more work is needed.

The effective dose of DDT used as a residual spray against adult anophelines varies in different circumstances from 60 to 200 mgm per square foot, and the optimum frequency of spraying is once in 8 weeks to once in 12 months. Many factors must be taken into account including the composition of the surface to be sprayed, and the habit of the mosquitoes concerned, before

Malaria

Vol 45, No 11]

rules can satisfactorily be laid down for any particular work. As larvicides the new compounds are very effective, and for DDT the effective dose is 6 quarts of a one per cent solution in kerosene or fuel oil per acre of stagnant water, and one part of DDT per million of water in running streams. Details are given of other formulations. In rural communities residual-spray-killing of adult anophelines is usually more economical than the use of larvicides, but this may not be so in urban centres. For species which rest indoors, residual spray may be enough, but for those which tend to rest outside, after feeding, indoors, anti-larval methods are needed also.

In section 6, on chemotherapeutics in malaria control, the committee accepts the proposition that in the existing state of knowledge measures against mosquito transmission are the only methods giving permanent control of malaria, but agree that chemotherapy and chemoprophylaxis are important in the clinical control of epidemic malaria, and that the latter, though secondary, is important for personal protection. Suppressive drugs are particularly useful for collections of workmen, for armies in the field, and for certain other groups.

Further information is needed on the results of taking synthetic drugs for many years, and on their effect on the state of immunity of people living in highly endemic conditions.

The various drugs in common use are discussed in some detail, and courses commonly used in treatment are quoted, for instance —

Mepacrine

| | 1st day | 2nd day | Succeeding days | Total |
|-----------------|---------|---------|-----------------|--------|
| Non-immunes | | | 0.3 × 5 days | 2.8 gm |
| | | 0.3 | 0.3 × 5 | 3.0 " |
| | 1.0 | 0.6 | 0.3 × 5 | 2.7 " |
| | 0.9 | 0.6 | 0.3 × 3 | 1.8 " |
| | 0.6 | 0.3 | | |
| Partial immunes | | | | |

These amounts are for adults and are administered in three or more daily doses.

The optimum suppressive dose for non-immunes is 0.1 gm daily, a preliminary build-up of 0.3 gm daily for five days is sometimes advocated.

Chloroquine

American experience indicates that the optimal adult dosage, expressed as base is as follows —

| | 1st day | Succeeding days | Total |
|-----------|---------------------------------|--|--------|
| U.S.A. | 0.6 gm (divided in two doses) | 0.3 gm daily for three days | 1.5 gm |
| Venezuela | 0.9 gm (divided in three doses) | 0.9 gm on second day only in three doses | 1.8 gm |

N.B. — The tablets of 0.25 gm of chloroquine diphosphate contain 0.155 gm of base. For suppression 0.3 gm. of base (0.5 gm of chloroquine diphosphate) is given once each week.

Paludrine

There is such wide difference in the effective range of dosage that the indications which follow must be regarded as provisional.

- (a) For standard therapy in adults paludrine monohydrochloride 0.3 gm. daily for five to ten days (the monohydrochloride contains 86.5 per cent. of paludrine base).
- (b) For single dose therapy in adults 0.3 gm. of monohydrochloride in one dose, followed by a weekly suppressive dose of 0.1 gm. to 0.3 gm. on the same day of the week.

The single dose method is not recommended for routine hospital treatment of *P. falciparum* malaria with paludrine. The committee notes that the best results with paludrine as a preventive have been obtained in the Far East, where 0.3 gm. given on one day each week may be enough, but in other parts of the world, and with other strains of *P. falciparum* this dosage may be insufficient (a daily dose of 0.1 gm. has, in fact, been advocated in West Africa, see WALLS, below).

The gametocides plasmoquine, pentaquine and iso-pentaquine are considered briefly.

In section 7 on research, a number of examples are given of studies which need to be undertaken either as basic research or as applied research. These examples are not discussed, and should be sought in the original by those proposing to initiate research.

Section 8 is concerned with quarantine especially with regulations for the disinsection of ships and aircraft which may introduce anophelines into countries which the authorities desire to protect: this section should be read in the original.

Sections 9 and 10 deal with recommended resolutions, and with conclusions and recommendations.

[The report as a whole represents a careful essay on some aspects of malaria control, which should be closely studied by governments and medical organizations in the tropics. A basic assumption is made that malaria causes ill-health, without much differentiation between the disability experienced in conditions of seasonal transmission and in those of perennial transmission with a resulting high degree of immunity in adults. The extent of malarial illness in the indigenous people of countries showing these degrees of transmission is not yet fully understood (and the Committee suggests research on the subject) and the effect of the various methods of control on communities subject to hyperendemic conditions is not satisfactorily known. Obviously if control is perfect and permanent, there would be no malaria, but partial control only is possible in many places and this may produce unexpected results. It would seem necessary that a long term observation should be carried out to attempt to assess the health importance of malaria in the various conditions of transmission, and of the effects of partial control in hyperendemic areas. The committee lays great stress on residual insecticides, and little stress on the older methods of drainage, water-control, biological control, etc. but it may be possible as the committee admits that races of anophelines not so susceptible to the action of insecticides (though none has yet been found) or having resting habits which do not bring them into contact with pyrethroid surfaces will be selected out, to replace those which now transmit the disease. It would be unwise to lose sight of the well-tried methods and the committee has probably no intention of doing so.

*ALVING, A S, CRAIGE, B, Jr, PULLMAN, T N, WHORTON, C M, JONES, R, Jr & EICHELBERGER, Lillian Procedures used at Stateville Penitentiary for the Testing of Potential Antimalarial Agents *J Clin Investigation* 1948, May, v. 27, No 3, Pt 2, 2-5

About 500 inmates of the Illinois State Penitentiary at Stateville volunteered to act as subjects for the controlled clinical testing of new antimalarial drugs. The results of studies already completed are set out in this special malaria supplement of the *Journal of Clinical Investigation*. The primary object of the studies was to obtain information about the effect of potential antimalarial drugs upon the relapse rate of sporozoite-induced *P vivax* malaria. The prophylactic and suppressive effects of the drugs were also studied, and observations were made on their toxicology and pharmacology.

All the subjects were white males in good physical health between the ages of 21 and 40, none had lived in a known malarious area and none had a history suggestive of previous malaria infection. There is no endemic malaria in Stateville. The Chesson strain (New Guinea) of *P vivax* malaria was used. This strain is characterized by a high relapse rate when such drugs as quinine or mepacrine are used in treatment, and by the almost complete absence of delayed primary attacks.

Anopheles quadrimaculatus was used for the transmission of infection. Each patient received the bites of ten infected mosquitoes. In the standard prophylactic procedure the drug to be tested was administered on the day before infection, on the day of infection, and on each of the following six days. Thick films of the peripheral blood were taken daily after the eighth day following inoculation.

In the curative tests the drugs were administered at intervals of four hours to obtain fairly constant concentrations in the body fluids. Slowly excreted drugs such as quinacrine, chloroquine and SN-8617 were given less frequently. The usual period of drug administration was 14 days.

Most of the drugs tested were members of the 8-aminoquinoline group of compounds for these the usual observations of temperature, blood pressure, urine analysis, and plasma drug concentrations, were supplemented by a leucocyte count every day and a differential count every fourth day, haemoglobin and methaemoglobin determination every day, and electrocardiogram after treatment.

JONES, R, Jr, CRAIGE, B, Jr, ALVING, A S, WHORTON, C M, PULLMAN, T N & EICHELBERGER, Lillian A Study of the Prophylactic Effectiveness of several 8-Aminoquinolines in Sporozoite-Induced *Vivax* Malaria (Chesson Strain) *J Clin Investigation* 1948, May, v 27, No 3, Pt 2, 6-11 [18 refs]

The four compounds studied, pamaquin SN-11,191, SN-1,452 and SN-13,276 (pentaquine) are all 6-methoxy-8-aminoquinolines. They all have high antimalarial activity in avian infections and their toxicity in the monkey is low. The methods of infection and drug administration are described above. Pamaquin 90 mgm [Pamaquin base] a day for 8 days beginning the day before inoculation protected two of five patients from infection, they exhibited no sign of malaria during 20 months of observation. Two developed fever and parasitaemia 18 and 19 days after sporozoite inoculation. One developed a delayed primary attack of malaria 106 days after infection.

*This and the following 21 abstracts represent summaries of a symposium on malaria which occupied a complete number of the relevant journal. They are therefore presented together, in the order in which they appeared.

Two of three subjects treated with SN 11 181 (90 mgm. a day) and two treated with SN 1 452 (240 mgm. a day) had no malaria during 20 months of observation. One subject in each of these two groups developed malaria within 3 weeks of inoculation.

The four subjects who served as controls for these first three drugs tested developed clinical malaria 12 to 14 days after inoculation.

One of five subjects treated with pentaquine (120 mgm. a day) developed fever and parasitaemia 22 days after inoculation. The other four have shown no evidence of malaria during 9 to 11 months of observation. The 12 control subjects for this experiment all developed clinical malaria in 12 to 19 days.

All of 8 patients receiving 180 mgm. of pentaquine a day remained free from malaria during nine months of observation although two of them received the drug for only two days and two others for only three days after the day of inoculation. The ten controls for this experiment all developed malaria 12 to 17 days after inoculation.

All doses mentioned above are in terms of base weight.

As the drugs were used in doses approaching the estimated maximum tolerated dose signs of toxicity were expected and found. Epigastric discomfort or pain (most severe in patients taking 180 mgm. SN 13,275) anorexia, nausea and vomiting were noted. Cyanosis was noted when the methaemoglobin exceeded 8 or 7 per cent. of the total haemoglobin. The average loss of haemoglobin was 1.75 gm. per 100 ml. of blood the greatest loss being about the 12th to 14th day after the start of medication.

The results show that all four drugs may act as true prophylactics for sporozoite-induced *P. vivax* malaria, but they did not protect all subjects. There was no positive correlation between plasma drug concentration and the prophylactic effect of these drugs. In subjects whose primary attacks of malaria were not prevented, the disease was so altered by the prophylactic treatment that it was rendered susceptible to cure by drugs ordinarily incapable of preventing relapse. It would seem that these drugs exert a deleterious effect upon pre-erythrocytic stages of the malaria parasite. Their relatively high toxicity precludes their general use as prophylactics.

PULLMAN T N, EICHELBERGER, Lillian, ALVING A S., JOHNS R., Jr, CRACK, B. Jr & WRIGHTON C M. The Use of SN-10,275 in the Prophylaxis and Treatment of Sporozoite-Induced *P. vivax* Malaria (Chesson Strain). *J. Clin. Investigation*. 1948 May v 27 No. 3 Pt. 2, 1st 16, 3 figs. [14 refs.]

SN 10,275 is 8,8-dichloro-2-phenyl-1-piperidyl-4-quinolinemethanol and has a close chemical similarity to quininae. Three subjects receiving 0.850 gm. (of base) a day for 8 days beginning the day prior to inoculation developed fever and parasitaemia, but the prepatent periods were from 6 to 9 times longer than in three control subjects. The plasma concentrations at the time of appearance of parasitaemia ranged from 66 to 110 gamma per litre.

After treatment with SN 10,275 the latent periods of those who relapsed were 26, 107 and 89 days. The median latent periods observed with quinine and quinacrine in the Chesson strain of malaria under the conditions of this investigation were 15 and 34 days respectively.

SN 10,275 remained in the plasma for long periods after medication was stopped. There was a wide variation in the rate of fall: the mean loss for the majority of the group was 20 per cent. per week, a much lower rate of disappearance than that shown by quinine or quinacrine.

Eight patients received SN 10,275 at a dosage of 1.0 gm. of the salt a day. One had mild gastro-intestinal symptoms: cramps, nausea and mild diarrhoea.

Another had fever of 102°F, headache and backache at the end of the 14-day course of treatment. All eight patients had photosensitivity of the skin, from a slight tingling of the face to severe burning sensations with erythema. One had some desquamation of the skin of the nose and another mild labial oedema. These symptoms appeared only after exposure to sunlight. The severity and duration of these symptoms are roughly correlated with the mean concentration of SN-10,275 in the plasma.

Toxic reactions and the variation in the rate of disappearance of the drug from the body limit the value of SN-10,275 as a suppressive drug, but further investigation of related compounds is indicated because a non-toxic drug with the antimalaria activity of SN-10,275 which remained in the body for long periods of time would have great value in the suppression of malaria.

CRAIGE, B, Jr, EICHELBERGER, Lillian, JONES, R, Jr, ALVING, A S, PULLMAN, T N & WHORTON, C M. **The Toxicity of Large Doses of Pentaquine (SN-13,276), a New Antimalarial Drug** *J Clin Investigation* 1948, May, v 27, No 3, Pt 2, 17-24, 4 figs [16 refs]

The purpose of the observations reported in this paper was to define the margin of safety of pentaquine (SN-13,276) in the treatment of malaria. In the therapeutic trials, five subjects received 120 mgm pentaquine base a day with quinine for 14 days. Five others received similar treatment but without quinine. In the prophylactic trials, five subjects received 120 mgm pentaquine base a day for eight days, and five 180 mgm a day for eight days. The doses used were double or treble the amounts necessary for antimalarial treatment.

The toxic reactions were severe. Most of the subjects had severe abdominal pain, nausea, anorexia and methaemoglobinaemia, similar to the symptoms produced by toxic doses of pamaquin. Serious physiological abnormalities developed in three of the subjects taking 120 mgm of pentaquine a day without quinine, therapeutically. They displayed postural hypotension with syncope, arterial and venous oxygen unsaturation, and loss of weight, which persisted for a long time after the end of treatment. The symptoms were possibly due to central impairment of the sympathetic nervous system.

ALVING A S, CRAIGE, B, Jr, JONES, R, Jr, WHORTON, C M, PULLMAN, T N & EICHELBERGER, Lillian. **Pentaquine (SN-13,276), a Therapeutic Agent effective in reducing the Relapse Rate in Vivax Malaria** *J Clin Investigation* 1948, May, v 27 No 3, Pt 2, 25-33, 2 figs [14 refs]

The procedure adopted at the Illinois State Penitentiary for the testing of antimalarial drugs has been described above. In spite of efforts to secure uniformity in the induced disease variations occurred. It was possible, however, to distinguish severe from less severe infections according to the length of the prepatent or preceding latent periods. Subjects with long prepatent or latent periods had a relapse rate of 67 per cent after treatment with so-called suppressive drugs. Those with short periods a relapse rate of 98 per cent. A small group of volunteers had massive infections, being bitten by 80 infected mosquitoes instead of the ten used in the standard procedure. Their relapse rate was 100 per cent. The subjects were accordingly divided into three categories representing a moderate a severe and an extremely severe challenge to the therapeutic efficiency of the test drug.

Pentaquine was given to 82 persons in daily doses of 60 mgm. of base or less for 14 days. When it was given alone in doses of 30 or 60 mgm. a day fever disappeared in two to four days, parasites disappeared in three to six days. Twenty-six moderately infected subjects were given 60 mgm. a day and four others 30 or 45 mgm. a day. These 30 subjects also received 2 gm. quinine sulphate daily. The relapse rate was only 3 per cent as compared with 67 per cent obtained when similar cases are treated with suppressive drugs. Of 1 subject with severe infections treated with pentaquine alone in doses of 15 to 45 mgm. of base a day all but one relapsed. Pentaquine 60 mgm. a day reduced the relapse rate of severely infected patients—only two of four relapsed. Seventeen severely infected subjects received this daily dose of pentaquine with 2 gm. quinine sulphate, for fourteen days—only three relapsed—a reduction in the relapse rate from 88 to 18 per cent. The extremely heavy infections all relapsed after pentaquine treatment.

Pentaquine should only be administered under close medical supervision. The daily dose of 60 mgm. should not be exceeded—this has the same toxicity as 30 mgm. of pamaquin base or 67 mgm. of its naphthoate salt. The toxicity of pentaquine is too great to warrant its use in prophylaxis or prolonged suppression.

ALVIN A. S. PULLMAN, T. W., CRAIG B. JR., JONES R. JR., WHORTON C. M. & EICHENBERGER, Lillian. The Clinical Trial of Eighteen Analogues of Pamaquin (Plasmochin) in *Vivax* Malaria (Chesson Strain). *J. Clin. Investigation*. 1948 May v 27 No. 3, Pt. 2, 34-45 4 figs. [25 refs.]

This is a record of work done in the search for a drug possessing the capacity of pamaquin to reduce the relapse rate of *vivax* malaria, but devoid of the toxic properties of that drug which hamper its extended use. The observations were made in the Illinois State Penitentiary—the procedure adopted is described above. Only pamaquin analogues with pamaquin-type toxicity in animals were used. They had previously been tested for antimalarial activity in avian infections and for toxicity in rodents, dogs and monkeys.

The eighteen 8-aminoquinolines tested were SN 191, SN 9,972, SN 11,191, SN 12,325, SN 14,354, SN 14,354, SN 12,431, SN 13,232, SN 13,233, SN 13,274, SN 13,276, SN 13,380, SN 13,429, SN 13,619, SN 13,694, SN 13,697, SN 14,011 and DR 15,302. It was at first planned to administer the maximum tolerated dose as estimated from the animal experiments. Severe toxic reactions caused by four of these drugs at this high dosage led to the abandonment of this plan. Thereafter—of the estimated maximum tolerated dose was administered—if toxicity for man was found to be absent, or mild, larger doses were tried.

Drugs were administered in equal doses every four hours over a period of fourteen days. Quinine was administered concurrently with the drugs, 2 gm. of the sulphate or dihydrochloride daily.

Eight of the drugs were ineffective in preventing relapse of severe infections in the doses used. Ten compounds apparently cured one or more patients with severe infections. Five exhibited pronounced activity inasmuch as the majority of patients treated with them had not subsequently relapsed (follow-up period from two months to one year). These drugs are SN 9,972, SN 13,274, SN 13,429, DR 15,302 and SN 13,276 (pentaquine).

No serious toxic symptoms were caused by any of the drugs on the reduced dosage—the most common symptoms were abdominal pain, nausea and vomiting. Cyanosis occurred when methaemoglobinemia exceeded 5 or 6 per cent of total haemoglobin. Mild drug fever, leucocytosis and leucopenia have been observed.

The studies indicate that the curative properties of pamaquin are shared by several analogues, but no definite conclusions can be drawn as to the specific molecular configuration required in a curative drug

Drug régimes which produced a high percentage of cures tended to prolong the subsequent latent periods in patients whom they failed to cure

PULLMAN, T N, CRAIGE, B, Jr, ALVING, A S, WHORTON, C M, JONES, R, Jr, & EICHELBERGER, Lillian Comparison of Chloroquine, Quinacrine (Atabrine), and Quinine in the Treatment of Acute Attacks of Sporozoite-induced *Vivax* Malaria (Chesson Strain) Preliminary Report *J Clin Investigation* 1948, May, v 27, No 3, Pt 2, 46-50, 2 figs [15 refs]

The antimalarial chloroquine (7-chloro-4-(4-diethylamino-1-methyl-butyl-amino)-quinoline) was synthesized during the late war in USA. Its activity was reported on by LOEB *et al* [this *Bulletin*, 1946, v 43, 708], and has now been compared with that of quinine and quinacrine (atebrin, mepacrine), under controlled conditions, in the treatment of primary attacks and early relapses of sporozoite-induced *P vivax* malaria of S Pacific origin (Chesson strain). For this purpose, 39 prisoner-volunteers were infected by the bites of 10 *Anopheles quadrimaculatus* or by injection of sporozoites from their salivary glands. Treatment was begun early in the attacks. On the first day, 0.8 gm chloroquine base was given, followed by 0.2 gm daily for 6 days (total 2.0 gm over one week). In the same period approximately 2.7 gm atabrine base and 11 to 12 gm quinine base were administered (or 21 to 23 gm of quinine base over 14 days) to different groups. The dosage approached the maximum which was well tolerated. Plasma levels of each drug were measured by the methods of BRODIE & UDENFRIEND [this *Bulletin*, 1943, v 40, 821 1944, v 41, 453, 1947, v 44, 793].

Parasites were generally removed from the blood most rapidly by chloroquine. The relapse rate for each drug was 90 per cent or over. The latent interval after drug administration was longest after chloroquine treatment, possibly owing to its slower excretion or degradation, or to the greater margin between minimal effective plasma level and that reached by the above dosage. The drug proved superior to quinine and atabrine under the conditions employed.

J D Fulton

JONES, R, Jr, PULLMAN, T N, WHORTON, C M, CRAIGE, B, Jr, ALVING, A S & EICHELBERGER, Lillian The Therapeutic Effectiveness of Large Doses of Paludrine in Acute Attacks of Sporozoite-induced *Vivax* Malaria (Chesson Strain) *J Clin Investigation* 1948, May, v 27, No 3, Pt 2, 51-5, 2 figs [17 refs]

Reports on the treatment of *P vivax* and *P falciparum* infections with paludrine have been reviewed [this *Bulletin*, 1946, v 43, 402, 821, 1947, v 44, 232, 1948, v 45, 34, 238, 491]. Its value in treatment of acute attacks following sporozoite-induced infections of *P vivax* of S W Pacific origin (Chesson strain, which is characterized by early onset of primary attacks, high relapse rate and short interval between attacks) has been compared with that of other suppressive drugs. The patients were healthy white prisoner-volunteers and were infected by the bites of 10 *A quadrimaculatus* or by injection of their salivary glands. Only primary attacks or early relapses were treated so as to avoid the factor of acquired immunity, and treatment was begun at the onset of fever or detection of parasitaemia. All drugs were given by mouth, and the dosage recorded represents that of the free base. Ten

patients were treated with paludrine and received 0.97 gm. daily for 14 days in equal doses given every four hours. The dosage for quinacrine (atebrin, mepacrine) was 0.87 gm. in four equal doses on the first day and 0.33 gm. similarly divided on the following 6 days. Pentaquine (6 methoxy-8(5 isopropylaminoamylamino)-quinoline) was given in 10 mgm. doses every 4 hours for 14 days. The method of SPINNA & TORTY (this *Bulletin* 1946 v. 43 207) was used for estimation of paludrine in plasma and one based on that of BLONDE *et al.* (this *Bulletin* 1947 v. 44 793) for pentaquine.

Quinacrine was more effective in terminating acute attacks than paludrine which cleared the blood of parasites less slowly than chloroquine (see above). When infections were severe radical cures were not obtained with these drugs, but paludrine was a valuable drug in treatment of acute infections, and its side effects were negligible. Some patients with less severe infections did not relapse after treatment with it or with quinine. The length of the latent period after treatment with paludrine was intermediate between that after treatment with quinine and atabrin. Neither quinoline nor pentaquine exhibited synergistic activity with paludrine.

J. D. Fulton

ALVING A. S. EICHELBERGER, Lillian CRAIG B. Jr. JONES R. Jr. WHORTON C. M. & PULLMAN T. V. Studies on the Chronic Toxicity of Chloroquine (38-7618). *J. Clin. Investigation*, 1948, May v. 27 No. 3, Pt. 2, 60-65 4 figs. [16 refs.]

These studies were undertaken to determine whether chloroquine could be taken for long periods as a malaria suppressive without causing serious toxicity. To establish the margin of safety larger doses than those necessary for suppression were given. The subjects were inmates of the Illinois State Penitentiary free from any physical disability or neurosis. There were two groups of twenty each. The members of the first group each received 0.5 gm. chloroquine base once a week, for a year. Members of the second group were given 0.3 gm. of the base daily in two doses, for 77 days, and then 0.5 gm. weekly as in the first group for the rest of the year. In the daily dosage studies, mean low plasma concentrations in excess of 200 gamma per litre were maintained for ten weeks. A plasma chloroquine concentration of 10 gamma per litre is sufficient for malaria suppression. Individual low values in excess of 500 gamma per litre occurred without unusual symptoms.

On the higher dosage usual disturbances headache bleaching of the hair electrocardiographic changes and slight loss of weight occurred. These symptoms are said to have caused no incapacity and they diminished or disappeared when the dose was reduced. Member of the group on the weekly dose suffered from occasional headaches and lost little weight. Two had a skin eruption resembling lichen planus.

It is concluded that chloroquine is a safe antimalarial preparation when given in the recommended dosage. The dosage recommended for the treatment of an acute attack of a or falciparum malaria is 1.5 gm. of chloroquine base in three days for suppression 0.3 gm. weekly.

Norman H. Kyle

SHANNO J. A. EARLE D. P. Jr. BERLIN R. W. & FUGATE J. V. Studies on the Chemotherapy of the Human Malaria. I. Method for the Quantitative Assay of Suppressive Antimalarial Action in Vivax Malaria. *J. Clin. Investigation*, 1948 May v. 27 No. 3 Pt. 2 66-74 4 figs.

It has now been demonstrated by SHANN and CLARK (this *Bulletin* 1948, v. 45 62) that in post-zytotic-induced *P. vivax* malaria and in infection with *P. cynomolgi* in monkeys tissue phase of the infection occurs. From the

persistent tissue phase erythrocytic forms may arise and thus bring about relapses. This tissue phase is absent in blood-induced infections and relapses do not occur. The activity of drugs has been classified as prophylactic, suppressive or curative, depending on the effects produced. The practical needs of war created a demand for active suppressive agents, and for assessment of their value blood-induced infections were widely used. The authors have investigated the validity of this procedure and have tested the susceptibility to quinine of the red cell forms which arise from inoculation of infected blood as well as from sporozoite inoculation. The susceptibility of different strains of the same plasmodium to this drug was also investigated. For this purpose standardization of conditions with regard to host and parasite were necessary in order to obtain reliable results.

White syphilitic patients with central nervous system involvement, having no previous history of malaria and therefore presumed to be susceptible, were employed. In the earlier experiments, the McCoy strain of *P vivax* was used and its biological characters are described. Thirty patients were inoculated with 500,000 parasites from an early primary infection and the course of parasitaemia was followed in blood smears. Therapy was started on the fourth or fifth day of fever and drug dosage was arranged to give a constant plasma level for 4 days. Estimations were made by the method of BRODIE & UDENFRIEND [this *Bulletin*, 1943 v 40, 821]. If blood smears became negative as the result of treatment, observation was continued over a period of 14 days, and if still negative reinoculation with twice the original number of parasites was carried out and observation continued for another period of 14 days.

The results of therapeutic treatment could be arranged into three classes. In the first, the drug was without effect, in the second a temporary effect was obtained with partial or complete disappearance of parasitaemia and fever, followed by recurrence within a specified period. In the third class, there was complete disappearance of parasites and the patient became susceptible to inoculation. The three classes were correlated with mean quinine plasma concentrations, indicating "that the susceptibility to quinine is a stable characteristic of the infective organism." The correlation between plasma-quinine levels and therapeutic effect was greater than between oral dosage and effect. The result obtained with a given drug concentration was independent of the degree of parasitaemia. Those obtained by similar treatment of 15 patients infected with the same strain of parasite by means of sporozoites indicated that the action of quinine against the resulting blood forms did not differ from its action against the same forms derived from blood inoculation. In similar experiments the Chesson strain of *vivax* malaria of New Guinea origin appeared to possess greater resistance to quinine than the McCoy strain. Certain characters of the Chesson strain are of special value in blood-induced infections for indicating the resistance of red cell forms to chemotherapeutic agents [This important paper should be consulted in the original by those interested.]

Studies on the Chemotherapy of the Human Malarias II Method for the Quantitative Assay of Suppressive Antimalaria Action in Falciparum Malaria *J Clin Investigation* 1948, May, v 27, No 3, Pt 2 75-9

In continuation of the work described in Part I of the series dealing with *P vivax* [above], the susceptibility of the erythrocytic forms of 2 strains of *P falciparum* to quinine has now been investigated as a basis for the assessment

of antimalarial activity. Similar studies projected for *P. malariae* had to be abandoned on account of practical difficulties. The patients as before were neurosyphilitics carefully chosen, and received an intravenous inoculation of 500,000 erythrocytic forms of the potentially virulent McLendon strain of *P. falciparum* from an untreated patient on the first or second day of fever and the course of the infection was followed in blood smears. Therapy was begun early in the infection to avoid danger to life. A loading dose of quinine was followed by others at 4- to 6-hour intervals in order to maintain a constant plasma concentration over a period of 4 to 8 days, which was checked by frequent drug estimations. After completion of the dosage schedule observation was started on the day after the final effective plasma level and was continued for 1 day in the event of disappearance of parasitaemia and fever. Remoculation with twice the original number of parasites was then carried out and observations were continued till parasites reappeared.

The therapeutic results were arranged in three classes as in the earlier experiments. In the 34 patients investigated, the results indicated that the therapeutic response to quinine was correlated with the duration of therapy (longer than in the experiments with *P. vivax*) and with the plasma quinine concentration. In similar experiments with another strain of *P. falciparum* (Costa strain) 21 patients were similarly investigated. The latter strain gives rise to a clinical picture like the other but the erythrocytic parasites from blood and sporozoite-induced infections nevertheless appeared to be more resistant to the suppressive action of quinine. The strains of *P. falciparum* employed showed greater resistance than the *P. vivax* strains to the suppressive action of this drug when judged in terms of plasma concentration. J. D. FULTON

TAGGART, J. V., EARLE, D. P. Jr., BERLINER, R. W., ZUBRON, C. G., WELCH, W. J., WISE, VANCE H., SCHROEDER, E. F., LONDON, I. M. & SUE, J. V. Studies on the Chemotherapy of the Human Malaria. III. The Physiological Disposition and Antimalarial Activity of the Cinchona Alkaloids. *J. Clin. Investigation*. 1943, May 1, 27 No. 3 Pt. 2, 50-66. (18 refs.)

Quinine has been the most widely used of the four chief cinchona alkaloids in the treatment of malaria, in spite of the fact that experiment has shown the others to possess comparable activity. On account of war needs further investigations were undertaken since supplies of cinchona bark containing the alkaloids other than quinine were readily available in the Western hemisphere. The present studies deal with the distribution, activity and toxicity of the four principal cinchona alkaloids in a quantitative manner with the aim of establishing a rational basis for their employment. The well known methods of BRODIE & UDENFRIEND this *Bulletin* 1943 40 821 1947 44 793 were used for their estimation in biological fluids. The therapeutic tests and classification of results were similar to those employed in Parts I and II of this series (above). Particular attention was paid to the relationship between oral dosage and resulting plasma concentration. Absorption, distribution, degradation and excretion were also studied after oral administration in soft gelatin capsules over a period of 4 to 8 days.

It was found that the plasma concentration resulting from a particular dosage of any of the alkaloids varied widely in different individuals. The highest levels were attained with quinine and were lowest with cinchonine probably because the latter was largely metabolized rather than because of its degradation in tissues. Peak values were reached with a single dose by mouth within 3 hours, but persisted for short time only and soluble salts produced a higher

level than the alkaloidal bases. Maintenance doses of each, however, gave rise to the same equilibrium plasma concentration. Absorption from the gastrointestinal tract was almost complete as judged by the small amount of material excreted in faeces (less than 5 per cent), which consisted mostly of unchanged alkaloids. The concentration of quinine and cinchonine in plasma was more than 5 times that in the blood cells. In animals it has been shown [this *Bulletin*, 1944, v 41, 11, 1945, v 42, 778] that the concentration of these substances in organs and tissues is many times that in plasma. In man there appears to be little localization in tissues and no cumulative effect. Only a small percentage of the administered dose was excreted unchanged in the urine. The percentage of degradation products so excreted varied widely for the different alkaloids. Renal excretion plays only a minor part in regulating plasma concentrations of the parent substances, and in the body they undergo metabolic alteration to a large extent. One of the chief products formed in each case is the 2-hydroxyquinoline derivative, first isolated from quinine by KELSEY *et al* [this *Bulletin*, 1944, v 41, 923]. The derivative from cinchonine was shown to possess very little antimalarial activity. KNOX [this *Bulletin*, 1946, v 43, 1005] showed that an enzyme from rabbit liver could bring about a similar oxidation in all four alkaloids, but there is no evidence that the same enzyme is responsible for the oxidation in man.

The plasma concentration required to interrupt *P vivax* or *P falciparum* infections varied with each alkaloid, but the antimalarial activities of the four alkaloids did not differ widely. Cinchonine, however, showed a lesser activity against one strain of *P falciparum*. Cinchonism was encountered with quinine, and other unpleasant side-effects occurred with cinchonine, but only one patient showed idiosyncrasy to the former. It appears from the results obtained that any one of the four alkaloids is effective in control of clinical attacks of malaria provided that doses are given every 6 hours in order to maintain effective plasma drug levels. On account of their excretion and metabolism, these cinchona products are probably not so effective for suppression as some newer drugs with different distribution in the body.

EARLE, D P Jr, WELCH, W J & SHANNON, J A. **Studies on the Chemotherapy of the Human Malaria. IV The Metabolism of Cinchonine in relation to its Antimalarial Activity.** *J Clin Investigation* 1948, May, v 27, No 3, Pt 2, 87-92 [12 refs]

The metabolic changes which a drug undergoes in the body may be of significance for the chemotherapeutic effect which it exerts. An investigation was undertaken from this viewpoint with cinchonine since it is known to undergo considerable metabolic changes in the animal body. KELSEY *et al* have carried out investigations in this field [this *Bulletin*, 1944, v 41, 11, 260, 1946, v 43, 404] while MEAD and KOEFLI [*ibid*, 1945, v 42, 9] showed that the substance obtained from quinine was the 2-hydroxy derivative. KNOX [this *Bulletin*, 1946, v 43, 1005] showed that there is an enzyme in rabbit liver which can oxidize the four chief cinchona alkaloids to a similar derivative. Most of the present data was obtained from normal patients. With the use of the method of FISHER *et al* (*J Pharm & Exper Therap*, 1943, v 79, 373) the amount of cinchonine and its 2-hydroxy derivative bound to albumin was found to be considerable. Absorption from the intestinal tract of the two substances was almost complete. From the urine, less than 5 per cent of the substance was recovered and more than 50 per cent of the 2-hydroxy derivative. The relationship between oral dosage and the blood plasma concentrations of each was determined by the well-known methods of BRODIE and UDENFRIEND.

[this *Bulletin* 1947 v 44 783] Results showed that when the parent substance or equal amounts of the two substances were given orally the resulting concentration of the derivative was greater in each case and its renal clearance was higher than that of cinchonine itself and was not depressed by doses of alkali to the extent that occurs with other organic bases. These differences were due largely to the greater rate of metabolism of cinchonine. The metabolite product was considerably less active than the parent substance against the McCoy strain of *P. vivax* when judged on the basis of plasma concentrations attained.

TAGGART J. V. EARLE D. P. JR. BERLINER R. W. WELCH W. J. ZIEBROD C. G. JAILLIE J. W. KUTCH Beatrice H. NORWOOD J. & SHANNON J. A. Studies on the Chemotherapy of the Human Malaria. V. The Antimalarial Activity of Quinacrine. *J. Clin. Investigation*. 1948 May v 27 No. 3 Pt. 2, 93-7 1 fig.

As a result of the development of simple and accurate methods for the estimation of quinacrine (atebrin, mepracrine) by BRODIE and LUNDENHILL and by MASEN [this *Bulletin* 1944 v 41 453 1945 v 42 8] in biological materials and in various studies, including those of SHANNON *et al.* [*ibid.* 1945 v 42 343] on its distribution in the body, the use of this drug in suppression and treatment of malaria was put on a rational basis. This report deals with the activity of the drug in terminating acute attacks of blood-induced *P. vivax* and *P. falciparum* malaria. The methods and strains employed were those described in earlier parts of this study. Suitable priming doses were given to obtain equilibrium plasma drug levels within a few hours, and the period over which drug was given was curtailed to prevent the continuance of significant drug levels in the blood beyond the desired 4 days in the case of *vivax* malaria and 8 days in the case of *falciparum* infections. The relationship between oral dosage, plasma concentrations and therapeutic effects are considered and indicate the range of effective plasma concentrations of the drug. The results obtained should be of value when the antimalarial activity of drugs of similar character is being studied. It is clear that the results depend to some extent on the species and strain of parasite used. The adequacy of dosage schedules in current use may readily be checked but details must be consulted in the original. J. D. Fulton

BERLINER, R. W. EARLE, D. P. JR. TAGGART J. V. ZIEBROD C. G. WELCH W. J. COXAN V. J. BAUMAN E. MUDDER S. T. & SHANNON J. A. Studies on the Chemotherapy of the Human Malaria. VI. The Physiological Disposition, Antimalarial Activity and Toxicity of Several Derivatives of 4-Aminoquinoline. *J. Clin. Investigation* 1948 May v 27 No. 3 Pt. 2, 98-107 1 fig. (20 refs.)

Russian workers before the late war appear to have regarded 4-aminoquinoline derivatives as of value in the treatment of malaria, but do not seem to have explored this group of substances to any extent. A number of derivatives, including S.N. 618 (Chloroquine) were synthesized in America during the war and certain members of the group appeared to show greater suppressive activity than quinacrine (mepracrine atebryn) which they may be regarded as having some structural relationship if the latter were to suffer the loss of a benzene ring.

The present investigation deals with their physiological distribution, antimalarial activity and toxicity and included the study of absorption from the gastro-intestinal tract, renal excretion, distribution in tissues, combination with non-diffusible constituents of plasma as well as the relationship between

Vol 45, No 11]

oral dosage and plasma concentration The methods of BRODIE, UDENFRIEND *et al* [this *Bulletin*, 1947, v 44, 793] were used for the drug estimations It was found that absorption of these substances was practically complete after oral dosage When equilibrium in plasma had been attained, 10 to 25 per cent of the daily dosage was accounted for by renal excretion, which was increased by the administration of acid and decreased by alkali as previously reported The unexcreted portion must suffer metabolic degradation All the drugs persisted in plasma for some time after the end of treatment The concentration of 4-aminoquinolines in the tissues of mammals was greater than in plasma There was some localization of the drugs in red and white blood cells As with quinine, these substances combined to a considerable extent with the non-diffusible elements of plasma

In testing antimalarial activity in blood-induced infections, the McCoy strain of *P vivax* and the McLendon strain of *P falciparum* were used, as described earlier The Chesson strain of *P vivax* was used for mosquito-induced infections The procedures were standardized and the results could be compared with those obtained with other drugs As a group, the 4-aminoquinolines showed high activity against both species of malaria The most active substances were derived from 7-chloro-4-aminoquinoline Administration of S N 7618 (Chloroquine) which is 7-chloro-4-(diethylamino-1-methylbutylamino)-quinoline in the dosage recommended [see this *Bulletin*, 1946, v 43, 708] over a period of one year showed that it was a safe suppressive agent, and S N 8137 (7-chloro-4-(3-diethylamino-2-hydroxypropylamino)-quinoline) showed similar characters and was of low toxicity J D Fulton

BERLINER R W EARLE, D P, Jr, TAGGART, J V, WELCH, W J, ZUBROD, C G, KNOWLTON, P, ATCHLEY, J A & SHANNON J A Studies on the Chemotherapy of the Human Malarial VII The Antimalarial Activity of Pamaquine *J Clin Investigation* 1948, May, v 27, No 3, Pt 2, 108-13 [16 refs]

Plasmoquine (pamaquin) was synthesized in Germany in 1926 by SCHULEMANN and his collaborators, and proved an active schizonticide in *P cathemerum* infections of canaries, but did not possess the same activity in human malaria Its most striking property was its activity against the gametocytes of *P falciparum* Its toxicity made it of limited value in treatment In combination with quinine it was believed to reduce the number of relapses in benign tertian infections SINTON [this *Bulletin*, 1930, v 27, 656] and JAMES, NICOL & SHUTE [*ibid*, 1931, v 28, 973] showed that it could act as a prophylactic in mosquito-transmitted malaria

The present authors have investigated the pharmacology and toxicity of pamaquin in order to get quantitative data on its suppressive activity in *P vivax* and *P falciparum* malaria and its curative action in sporozoite-induced *vivax* malaria, with a view to further development of this class of compound Dosage was arranged to produce uniform plasma concentrations over periods of 4, 6 or 8 days, depending on the infection used, when the ability of the drug to suppress blood-induced infections was being studied The standard method of estimation [this *Bulletin*, 1947, v 44, 793] was employed The suppressive action was more marked against *vivax* than against *falciparum* infections, but strain differences were apparent, and in both the drug was relatively ineffective even at high dosage The low activity against the blood forms in *vivax* malaria made it difficult to determine whether the tissue phase of the parasite was affected At a dosage of 60/90 mgm daily in conjunction with 2.0 gm quinine over a period of 14 days it had a curative action in primary infections of

The following table records the maximum methaemoglobin values in patients who had received pamaquin for five or more days, by which time they attain a fairly stable level —

| Treatment group | Number of subjects | Mean per cent methaemoglobin | Standard deviation | Range per cent methaemoglobin |
|------------------------|--------------------|------------------------------|--------------------|-------------------------------|
| pamaquin, 90 mgm daily | 24 | 12.2 | 7.0 | 0.9-28.7 |
| 60 " " | 13 | 8.9 | 4.5 | 1.9-20.8 |
| 30 " " | 29 | 4.4 | 2.4 | 0.7-10.0 |
| 30 " " | 6 | 12.2 | 4.6 | 6.0-19.3 |
| plus mepacrine | | | | |

The mean methaemoglobin values are proportional to the daily dose of pamaquin except for the small group that received quinacrine in addition here the values are equal to those recorded in subjects receiving a threefold larger dose of pamaquin. About half the patients in the first three groups were also receiving quinine, an addition that had no influence on methaemoglobin levels.

Acute haemolytic anaemia is the most serious hazard of pamaquin administration. It occurred in seven of 157 patients given pamaquin naphthoate in repeated doses for 2 to 14 days. Six cases occurred among 76 coloured patients, but only one among 81 white subjects.

The administration of 90 mgm of pamaquin a day for 14 days causes a significant reduction of mature neutrophile granulocytes. This reaction does not occur with daily doses of 30 mgm unless mepacrine is also administered. The process rapidly disappears when pamaquin administration is stopped.

EARLE D P JR, BERLINER, R W, TAGGART, J V, ZUBROD, C G, WELCH, W J, BICELOW, F S, KENNEDY, T J JR & SHANNON, J A. *Studies on the Chemotherapy of the Human Malaria. X The Suppressive Antimalarial Effect of Paludrine*. *J Clin Investigation* 1948, May, v 27, No 3 Pt 2, 130-33 [13 refs]

The therapeutic trials described were carried out in patients with blood-induced malaria. The infections were the McCoy strain of *P vivax* (28 patients), the Chesson strain of *P vivax* which is more resistant than the McCoy strain to quinine, mepacrine and chloroquine (16 patients), and the relatively quinine-resistant Costa strain of *P falciparum* (9 patients). Paludrine in varying doses, was administered by mouth. All doses are reported in terms of the free base. The therapeutic results are classified as follows: Class I, no certain effect, absence of parasitaemia for 14 days in McCoy strain or 21 days in Chesson strain or Costa strain; Class II, temporary suppression of parasitaemia for 14 days in McCoy strain or 21 days in Chesson strain; Class III, results with paludrine as low as 50 mgm produced Class III results with regularity. It was only slightly less effective against the Chesson strain of *P vivax*. The Costa strain of *P falciparum* was much more resistant. Total doses of paludrine ranging from 338 to 750 mgm were given to the nine patients, yet described in this malaria, it is apparently non-toxic in therapeutic doses.

BERLINER R. W., KENNEDY T. J., Jr., & BIGELOW F. S. A Technique for the Detection of Minimal Numbers of Malaria Parasites Its Application in the Detection of Suppressed Virax Malaria. *J Clin Investigation* 1948, May 27 No. 3 Pt. 2 134-7

A technique is described for the detection of minimal numbers of *P. vivax* parasites in the circulating blood.

Fifty to 15 ml. of venous blood are drawn into a syringe containing sufficient heparin to prevent clotting. The blood is centrifuged for 20 minutes at 2,000 r.p.m. The plasma layer is carefully removed. The white cells are then aspirated off as completely as possible. The plasma is poured back and gently mixed with the red cells. The reconstituted blood is then carefully layered over an equal volume of bovine albumin solution in a centrifuge tube. (The albumin is prepared by diluting four parts of a 30 per cent. bovine albumin solution with one part of normal saline solution.) The tube is centrifuged for five minutes at 1,000 r.p.m. and then at 2,500 r.p.m. for 15 minutes. The material is now in three layers. The upper layer the plasma is discarded. The deepest layer consists of the normal red blood cells that have passed through the middle albumin layer. The latter contains the parasitized red cells which because of their diminished density and the viscosity of the albumin solution have been left behind. The albumin layer is removed and mixed with two or three volumes of isotonic saline in a centrifuge tube and centrifuged at 2,500 r.p.m. for five minutes. The red cells which have been driven to the bottom where they usually form a layer just sufficient to cover the bottom of the tube are transferred to a clean slide to form a thick smear which is dried and stained with Giemsa in the usual way.

With this technique the authors were able to confirm the observations made by FAIRLEY (this Bulletin 1945 4, 630) by subinoculation that the parasites of *P. vivax* first appear in the circulating blood 8½ days after the bite of infected mosquitoes and that the time of appearance is not influenced by suppressive drugs.

Attempts to concentrate parasites in *P. malariae* infections did not succeed the parasitized cells are not enlarged. The same is true of cells containing young ring forms of *P. falciparum*.

ROSENFELD M. ZUBROD C. G. BLAKE W. D. & SHANNON J. A. Methemalbumin. I. Appearance during Administration of Pamaquine and Quinine. *J Clin Invest* 1948 May 27 No. 3, Pt. 2, 133-43 8 figs. [18 refs.]

A new compound of albumin and haematin which does not occur in normal serum, was described by FAIRLEY and BROWNFIELD in cases of blackwater fever and later in cases of severe malaria nocturnal haemoglobinuria pernicious anaemia and other conditions, as well as after injection of large amounts of haemoglobin or of haematin. The compound was later named methemalbumin and its formation and properties described (this Bulletin 1945 32, 828 1947 39 270 271). It had also been observed by their authors in different conditions including pamaquine haemoglobinuria. The reaction between the two components was further investigated by HELLIN (ibid. 1944 41 1048).

Its appearance was observed consistently by the present authors during combined pamaquine-quinine therapy but not when either drug was given alone.

Investigations were therefore carried out on four groups of male white volunteer malarial patients infected by mosquitoes with the Clonox strain of *P. m.* One group received pamaquine and quinine a second group pamaquine

alone, a third quinine alone and a fourth pamaquin and quinacrine [atebrin, mepacrine]. Oral treatment was begun on the 5th day of fever, and two days later in the cases receiving pamaquin, being continued over a period of 14 days. Clear unhaemolysed serum was obtained before and after treatment from fasting patients, without the use of an anticoagulant, by centrifuging the blood for $\frac{1}{2}$ hour when drawn. Methaemalbumin shows characteristic absorption and measurements were made in the Beckman spectrophotometer between 300m μ and 650 m μ , with diluted or undiluted serum according to the amount of pigment present. Chemical methods were also used for identification. The most intense absorption band occurs at 405m μ and was used for estimation in the absence of free haemoglobin. Allowance was made for absorption due to bilirubin which was estimated by chemical methods. Methaemalbumin was present in the serum of all patients of the group receiving combined pamaquin and quinine therapy, although in widely different amounts, and continued to increase during the period of treatment. Five days after therapy ended it was no longer present in measurable quantity, and was always absent from the serum of the other three groups. It was formed in the absence of frank haemolysis with which in the past it was most frequently associated. Methaemoglobin was also present in the red cells of patients receiving pamaquin alone or combined with quinacrine and quinine. The causal relationship between these two pigments, if any, is not clear.

J D Fulton

BLAKE, W D Methemalbumin II Effect of Pamaquine and Quinine on Pathways of Hemoglobin Metabolism J Clin Investigation 1948, May, v 27, No 3, Pt 2, 144-50, 4 figs [21 refs]

It has been noted in Part I of this investigation [above] that methaemalbumin occurs during intravascular haemolysis and in a number of other conditions as well as after administration of pamaquin and quinine in combination. The regularity with which the pigment was produced by the two drugs together offered a means of studying its metabolism. The relationship of methaemalbumin production to haemolysis, the effect of drugs on its rate of disappearance as well as the part played by the liver, have been investigated in white patients with syphilis of the central nervous system. Some patients were investigated after malarial therapy when liver function had become normal. Pamaquin and quinine were given orally and their levels in plasma determined at regular intervals to ensure that absorption was taking place. Solutions of haematin and haemoglobin were given intravenously with few untoward results. Estimation of these two substances were made, and also of coproporphyrin, serum bilirubin and faecal urobilinogen.

The increase in amount of the faecal urobilinogen over controls was used as a measure of increased haemoglobin katabolism and occurred during combined therapy with pamaquin and quinine. When haemoglobin was given intravenously in an amount equal to the increased breakdown of this substance caused by combined therapy, no measurable formation of methaemalbumin occurred in normal subjects. It was concluded that haemolysis alone did not give rise to formation of this substance. Intravenous administration of haemoglobin in combination with oral quinine gave rise to the pigment, but when the three substances gave rise to the same degree of methaemalbuminaemia as pamaquin replaced quinine only traces of it were formed. A combination in combination of quinine with haemoglobin. It seems probable that the drugs haemoglobin broken down and also by interference in some way with the pathway of metabolism the first effect being a synergistic one and the latter due to quinine alone. It emerged that the rate of disappearance of haemoglobin

from serum was not affected by the drugs, but they did appear to slow down the rate of disappearance of the methaemalbumin formed. The effect of pamaquin in delaying conversion of methaemalbumin to bilirubin may be a result of interference with liver function, thus causing the former substance to accumulate on intravenous administration of haemoglobin. Quinine on the other hand, acts in some way by increasing the degradation of haemoglobin in the vessels to haematin.

Methaemalbumin is regarded as a normal product of haemoglobin metabolism whenever free haemoglobin is present in the serum. Severe haemolysis is necessary before methaemalbuminaemia becomes apparent, unless it is allowed to accumulate in serum as a result of its conversion to bilirubin being slowed down. The accompanying diagram indicates a possible metabolic pathway of intravascular haemoglobin.

DE AZEVEDO J. F. CAMBOURNAC F. J. C. & PINTO M. R. Observações sobre a incidência do zoonosismo na Guiné Portuguesa. (Nota preliminar) [Observations on the Incidence of Malaria in Portuguese Guinea—a Preliminary Note.] *An. Inst. Med. Trop. Lisbon*. 1947 Dec. v 4 7 15 1 folding map. English summary

This note embodies the first results of an investigation initiated in Portuguese Guinea in January and February 1944 as part of the investigations launched by the Mission of the Tropical Medicine Institute of Lisbon. A total of 4 000 thick blood films were examined at first and eventually it was possible to deal with some 10 000.

Detailed regional findings are shown in a lengthy table and the incidence is shown graphically on a sketch map. *Plasmodium falciparum* was the common species, with *P. malariae* next; no *P. trax* were found. Distribution of infection during the dry season was much more irregular than might be expected. There was no correlation between the percentage of persons infected with the particular species of parasite and the distance from the coast of the places where they were found.

H. J. O'D. Burke-Giffney

YORRI, M. Non-Pigmented Malaria Parasites in the Bone Marrow from a Mixed Infection of *Leishmania* and *Plasmodium falciparum*. *T. M. Soc. J. p. Med. & Hyg.* 1948, July v 4, No 1 93-100 1 pl.

This paper records the finding in bone marrow smears of *Leishmania* parasites accompanied by malaria parasites resembling *Plasmodium falciparum* except for the important fact that the latter were devoid of pigment. The malaria parasites asexual and sexual, were all in red blood cells, but for the

absence of pigment, had normal morphology. In examination of the peripheral blood before sternal puncture, no malaria parasites were found. Without examination of the slides, no useful comment can be made.

KETTLE, D S The Growth of *Anopheles sergenti* Theobald (Diptera, Culicidae), with special reference to the Growth of the Anal Papillae in varying Salinities. *Ann Trop Med & Parasit* 1948, Apr, v 42, No 1, 5-29, 15 figs [26 refs]

This is a detailed study of the growth of the larva of *Anopheles sergenti* such of the paper is taken up with a statistical analysis of the recorded measurements, this part of the paper it is not possible to summarize, but in general, the object was to discover whether the anal papillae of larvae of anopheline mosquitoes grow during an instar and if so if their growth rate is the same as any other part of the body. In preliminary experiments, second stage larvae of *A. multicolor* were used, when it was observed that the thorax grows in length and breadth throughout the instar but there is no sudden increase at ecdysis. The head breadth remains more or less constant during the instar but shows a relatively enormous increase immediately after ecdysis. The second abdominal segment and the dorsal anal papillae grow steadily in length throughout the whole of the larval life. It is possible therefore to separate the different instars of *A. multicolor* on the head breadth. But this species was rare and as *A. sergenti* was plentiful, the latter was used for this investigation.

Five hundred larvae were used, 125 in each instar. Seven measurements were made on each larva: length and breadth of head, thorax and second abdominal segment and the length of the dorsal anal papillae. The larvae in each instar were divided into six classes based on the size of the thorax breadth. In diluted sea-water (equivalent to a 0.25 per cent solution of NaCl) the thorax and second abdominal segment grew steadily, while the anal papillae lengthened during the instar and increased suddenly at ecdysis.

The growth of the dorsal anal papillae was further investigated in larvae reared in various dilutions of sea-water. The eggs from several females were mixed and then divided into eight batches which were reared under similar conditions other than the salinity of the water. Fourth-stage larvae having a thorax breadth of $1,000\mu$ were taken as standard, and of those kept in distilled water the papillae were very long (313μ), in tap water they were smaller (210μ) and in sea-water (equivalent to 0.1 per cent NaCl) they were 190μ . There was no change as salinity increased to 0.75 per cent NaCl but in 1.0 per cent and 1.1 per cent they were distinctly shorter (152μ).

The author discusses various suggestions which have been put forward to account for this variation in the lengths of the anal papillae of larvae reared in different salinities and concludes that while the enlargement in distilled water is regarded as a functional hypertrophy connected with the uptake of chloride ions, the nature of the mechanism which regulates the length of the papillae is unknown. Whatever it may be, he suggests it is the same as that which controls the chloride content of the haemolymph.

FAIN, A & HENRARD, C Quelques moustiques du fleuve Congo (Chenal) et des rivières Kasai et Kwango [Some Mosquitoes of the Congo, Kasai and Kwango Rivers]. *Ann Soc Belge de Méd Trop* 1948, Mar 31, v 28, No 1, 7-20 [11 refs]

A list is given of the mosquitoes collected in African huts and European houses in villages along the Congo River from Léopoldville north to Kwamouth.

east along the Kasai to Banningville and south along the Kwango for about 80 kilometres. Altogether nine anophelines and twenty six culicines are recorded. Generally speaking, in the riverine villages *Anopheles maculipes* was predominant, which may have been due to the time of collecting, after 7 p.m. Small numbers of *A. gambiae* were occasionally taken, but along the Kasai river *A. wellcomei* became so abundant that at Wusman Pool it outnumbered *A. maculipes*. *A. funestus* was taken once at one village in the interior where, however *A. paludis* was the common species. H. S. Lewis

LEWIS, D. J. The Mosquitoes of the Jebel Aulia Reservoir on the White Nile. *Bull. Entom. Res.* 1948, May v. 38 Pt. 1 131-57 1 map, 6 figs. on 1 pl. & 3 text figs. [30 refs.]

The Jebel Aulia Reservoir is situated in the Sudan and extends some 530 kilometres up the White Nile from the dam of the same name. This area comprises the reservoir thousands of acres of seasonal swamps, irrigated areas and rain-water pools. The author discusses the topography, climate, population, vegetation, predaceous insects and fish and the effect of the dam on the breeding places of mosquitoes, of which forty-three forms have been found in the area.

Collections of mosquitoes were made during several visits to the reservoir between 1937 and 1946. Some results of collecting under various conditions in the Kawa section (the middle third) are summarized in four tables. Malaria occurs throughout the area and appears to have increased since the dam was constructed.

Anopheles gambiae is probably the main vector of malaria, and its breeding places which are comparatively small and well defined, can be treated with DDT in oil or with Paris green. *A. rufigipes* is provisionally regarded as a vector though of less importance than *A. gambiae* its control would be a considerable problem as its breeding places are more extensive. Pyrethrum spray is used in houses against this species and parts of swamps are treated with Paris green dust or DDT in oil. *A. pharoscis* is present in millions though of little importance as a malaria vector. The treatment against larvae is similar to that of *A. rufigipes*. *A. f. vesitus* occurs in the south, in the J belein section, though its northern limit is some miles further north in the Kawa section. Intensive house spraying appears to be the feasible method of control in the few villages that exist.

Paris green dust seems to be the ideal larvicide in this area because as it drifts with the wind its application does not necessitate wading in channels which may be infected with schistosome cercariae. An improved Paris green talquer is described and illustrated. H. S. Lewis

ROBERTS F. H. & O'BULLIVAN, J. Studies on the Behaviour of Adult Australasian Anophelinae. *Bull. Entom. Res.* 1948, May. 38 Pt. 1 159-74 graph & 1 pl. 10 refs.

Observations were made on adult anopheline mosquitoes at Cairns, North Queensland from January to April, 1944. & Salamaua, New Guinea from

May to July, and at Mirivasi, New Guinea from August to October. The species studied were *Anopheles punctulatus*, *A. p. farauti* and intermediate forms, and *A. amictus hilli*. The authors record in detail their investigations into prevalence and activity, by day and by night, biting habits, daytime haunts, host preferences and methods of determination of the age of female mosquitoes by condition of the wings, ovarian development and state of digestion.

All forms of *A. punctulatus* have much in common, though behaviour may differ slightly according to local conditions. Adults usually disperse from breeding places and congregate around the source of the blood meal, for example, human settlements. Greatest activity commences after dark but no marked periodicity was observed at dawn and dusk, as has been widely held. They do not indulge in long continuous flights but females have been found a mile from breeding places and males 600 yards away. After feeding, the females rest in the huts a short time, then fly out, their outdoor resting places are among vegetation near the ground, other females and males also are there and fertilization is assumed to take place here, not at the breeding place, males do not normally enter houses but stay in the bush. Pyrethrum sprays in huts in the daytime have therefore little effect, but the application of DDT to the walls is more promising. Precipitin tests showed that *A. p. farauti* has no pronounced preference for either animal or human blood but in *A. p. punctulatus* anthropophilism was marked. All forms seemed more attracted to the indigenous people in Salamaua than to the white man.

The behaviour of *A. amictus hilli* is similar in most respects to that of the *punctulatus* forms. One difference was, however, noted. *A. a. hilli* gathers in large numbers around the breeding places, where the males remain, and fertilization probably takes place here and not in the bush. The daytime resting places of females awaiting a meal were not determined and the host preferences were not fully explored by the precipitin test, but this anopheline is known to be a vicious pest in Northern Queensland.

Very little is known of the habits of other anophelines. *A. bancrofti bancrofti* rarely attacks man at Cairns, but in the Northern Territory has been reported to have an infection rate of 4.3 per cent. *A. annulipes* is an extremely common species, well distributed throughout Australia and extending into New Guinea. It is probably a malaria vector in sporadic cases outside the *farauti* area. [See also this *Bulletin* 1945, v 42, 1049, 1947, v 44, 275.] H S Leeson

COUTINHO J DE O. Contribuição para o estudo da distribuição geográfica dos anofelinos do Brasil. Sua importância na transmissão da malária [Geographical Study of Anophelines in Brazil and their Importance in Transmission of Malaria] [Thesis] Universidade de São Paulo, Faculdade de Medicina 1947, Dec, 117 pp, 2 maps [Bibliography]

According to the present author there are in Brazil 48 species of *Anopheles* and 3 of the related genus *Chagasia*. A table gives the distribution of the *Anopheles* in the separate states of Brazil

The bulk of the paper takes separate states and in each shows the local distribution of the species of *leishmaniasis* which occur the proportion of adults found in houses and so forth. The thesis contains a wealth of local detail.

In Brazil, *Plasmodium* has been found in six species of *leishmaniasis*. The salivary gland rate was 1.53 per cent. of 579 *L. darlingi* the rate was between 0.35 and 0.20 per cent. in considerable numbers of *L. trumppii*, *L. cruzi*, *L. infantum* and *L. braziliensis*. It was 0.07 per cent. in 3,838 *L. albanus*.

LAMPREY H. Induzierte Malaria nach Bluttransfusion. [Malaria transmitted by Blood Transfusion.] *Med. Klin.* 1947 May v 42, No. 9 371-2.

Owing to the risk of disease being transmitted by blood transfusion a law was passed in Germany in March, 1940 that donor must be free from tuberculosis, skin disease, venereal or tropical diseases. In spite of every care this freedom from infection cannot always be guaranteed. The author quotes the case of a man who in May 1943 was given a transfusion of 450 cc. of blood on account of anaemia produced by peptic ulcer. Great pains had been taken to eliminate risk of the diseases mentioned, but just a month later on the 7th, 9th, 12th and 14th days of June, the patient had attacks of fever and shivering, and examination revealed tertian malaria parasites in his blood. The donor had not had a day's illness for more than 20 years, but a history was obtained (although no parasites could be seen in two examinations of his blood) that in 1915 or 23 years before, he had been a prisoner of war in Southern Russia and had there suffered from malaria, tertian type, but though he had occasional attacks for 5 years afterwards, he had been quite free from them since 1920 that is 23 years before his blood was used for transfusion. All other sources seemed to be excluded.

ARU L. La ricerca del parassita malarico mediant arricchimento. (Nota di tecnica.) [Enrichment Method for finding Malaria Parasites.] *Riv. di Malariologia* 1948, Feb., v 27 No. 1 47-5, 3 figs. English summary.

After brief reference to methods of detection of malaria parasites, by special staining, by thick drop and enrichment methods, the author describes the one used at the Institute of Hygiene and Bacteriology of the University of Cagliari and Sardinia. Five cc. of blood are taken from a vein into citrate and centrifuged at a low speed for 15 minutes with a capillary pipette are drawn off, first the serum (? plasma), then the layer of leucocytes and the platelets which lie above the red corpuscles. Care is needed because if many white cells are left the resulting preparation is confused. The parasites are fixed by 10 per cent. formal for 20 minutes and the red cells haemolysed in 20-30 cc. of 0.35 per cent. NaCl for 10-15 minutes. The whole is then centrifuged for 5 minutes the supernatant fluid is removed leaving two or three drops for emulsifying the deposit. Preparations are spread from this dried in the thermostat or at room temperature and stained with Giemsa's stain, 10 per cent. The author claims that this procedure gives permanent preparation and a concentration of 50-150 times the original.

V. HALLER E. Über die Ursache und das Auftreten von Rückfällen bei der Malaria tertiana. [An Examination of the Origin of Relapses in Tertian Malaria.] *Med. Klin.* 1947 May v 42 No. 10 41-1. 7 charts.

The essence of this paper is to be found in the theoretical considerations which have convinced the author that in benign tertian malaria an R.E. or tissue cycle which he presumes to be in the endothelial cell of the capillaries, must take

The reasoning which has led him to these conclusions is now well understood, but he is, of course, ignorant of the recent classical demonstrations by SHORTT and GARNHAM. A detailed review of this communication has now lost its chief point, though it is interesting to observe how near to the real truth his arguments are. He observes, for instance, how in the Sardinia-infected military cases relapses of *P vivax* were extremely uncommon, whilst in a prisoner-of-war hospital on the Adriatic coast nearby they were invariably the rule. This anomaly he would explain by the disparity in the primary dose of sporozoites. On the persistence of the EE cycle the spring and autumn relapse of primary infections can also best be explained. He asserts too that timing of relapses is due to the presence or absence of immune bodies in the blood stream, which destroy the merozoites on liberation from the tissue stages—another prophecy which bids fair to come true, and he suggests that these immune substances can exert no action on the EE forms. In this respect the reaction is the same whether the primary infection is slight or severe. Any therapeutic measures which are directed towards the extirpation of the erythrocytic stages cannot prevent relapses from occurring at their predestined intervals, so that the only reasonable therapy is one directed towards the destruction of the tissue stages of the parasite. The absence of any provocative factors cannot be regarded as of any prognostic significance.

All these arguments now resound with a genuine ring P Manson-Bahr

A general review

MAIER, J *The Absorption of Quinine and Quinacrine in Dysentery Patients.* *Amer J Trop Med* 1948, May, v 28, No 3, 397-400

During the recent war American troops in New Guinea frequently suffered from malaria and dysentery at the same time, in spite of the fact that quinacrine (mepacrine) in 0.1 gm. daily doses was supposed to be taken as a routine. It seemed possible that in these circumstances the drug was not being absorbed. Investigations were therefore carried out on patients with severe or moderately severe dysentery to determine whether oral quinacrine or quinine was normally absorbed or whether some other form of administration was necessary. The patients were divided into three groups and received treatment according to the following dosage schedules. Group I, consisting of 14 patients, were given 40 grains of quinine daily as well as intensive sulphaguanidine treatment, non-dysentery patients were used as controls and received the same drug treatment. A similar number of patients in Group II received intensive sulphaguanidine treatment along with 3 doses of 0.3 gm quinacrine on the first day and 3 of 0.2 on the second day. Plasma levels of both drugs were determined by the method of BRODIE & UDE-FRIEND [this Bulletin, 1944, v 41, 453]. The 19 patients in Group III were given 3 doses of 0.3 gm quinacrine only on the day of admission and the plasma drug level was measured. Quinacrine plasma

levels were also measured in two patients without dysentery but who were also receiving sulphaguanidine. This substance did not interfere with quinaquine estimations.

There was no relationship between the severity of diarrhoea and the plasma levels of the drugs. It was concluded that the drugs were absorbed in the normal way when given by mouth to patients with diarrhoea as the result of acute bacillary or non-specific infection.

KARLSTORF A. Leber eine Leberschädigung durch hohe Atabrin-Dosen.
[Damage to the Liver from Large Doses of Atabrin.] *Nachricht.* 1947
July 15 v. 24/25 Nos. 39-40 637-3.

Considering how widespread has been the use of atabrin (mepacrine) in malarial conditions, reports of untoward by-effects have been surprisingly few. Except for gastro-intestinal disturbances, on the whole mild in degree, the chief have been mental or psychic—a sense of fatigue and depression leading perhaps to thoughts of suicide.

In the present contribution the author records the case of a young soldier 21 years of age hitherto enjoying the best of health. He gave a history of having taken in 3 weeks 10 small tablets of atabrin and in the following week 10 large tablets—at least 5 gm. altogether (probably more). He became jaundiced and was admitted to hospital. The upper part of the abdomen was tender to pressure but the liver was not at that time enlarged. During the ensuing fortnight the jaundice increased. The urine gave a strongly positive acridine reaction, the Takata-Ura reaction of the serum was marked and the liver was enlarged and could now be felt three fingers breadth below the costal margin—there was increased excretion of galactose in the urine after 50 gm. were taken—in successive hours 1 gm., 1.23 gm. and 0.5 gm., or 1.73 gm. altogether.

The hepatic condition, it was concluded, was due to the atabrin taken. Further investigations are to be undertaken to determine the pathogenesis of the action of the drug, and whether the damage to the parenchyma is due to its action on the liver capillaries.

WALLS E. S. Paludrine. Correspondence. *Brit Med J.* 1948, July 4
225-8.

Walls writes from Sierra Leone. He has not found that paludrine in doses of 0.1 gm. twice a week can be relied upon to prevent attacks of malaria in himself or his patients, but in doses of 0.1 gm. each day it is about equal to quinine and mepacrine in its suppressive effect and has the advantage that it is not toxic and does not stain the skin. For treatment he gives 0.1 gm. three times each day for 10 days and on the first day he also gives two doses of quinine (10 grains each).

In general, he prefers paludrine to the other drugs, but in doses greater than those hitherto recommended by the maker.

ROBERTSON J. D. Paludrine Treatment of School Children. *Zentralbl. Bakt.* 1947
Suppl. 1 v. 31 1-3 or *Med. J. Ind.* 1947, April 11 45.

The investigation reported by Dr. J. D. Robertson is the first in Zanzibar. About 50 children in each of three schools of essentially African population received 0.1 gm. paludrine twice a week from September 1947. In addition the children of a top school were given it and all children on the main island. A fourth group of pupils from one of the schools received no paludrine or

other medication and served as a control The children were examined for spleen and parasite rates before treatment and again in 6 weeks and 3 months The parasite rate, which averaged 50 per cent initially, fell to nil in the treated children in 6 weeks, and although it "tended to fall naturally" the controls still showed a rate of 26.8 per cent after 3 months Splenic enlargement fell from 60 per cent to 18 per cent over the period of treatment, but remained at 56 per cent in the untreated controls The haemoglobin levels were unchanged in all groups and the iron supplement caused no improvement The figures for the rates in each group are shown in three tables the author concludes that the dosage of paludrine, 0.1 gm twice weekly, was a little too small to be completely effective

ANSARI, M Y **Anti-Malarial Drugs Old and New, with some Observations on Paludrine in Malaria** *Indian Physician* 1948, July, v 7, No 7, 177-84

This paper is largely a review of the relative efficacy of the different anti-malarial drugs, but it contains a personal observation by the author on the use of paludrine in the treatment of about 20 patients suffering from benign tertian and malignant malaria [further details of the cases are not given] The drug was used in dosages ranging from 50 mgm to 300 mgm daily, and was administered as (1) a single initial dose of 300 mgm and then 100 mgm weekly for 6 weeks, (2) twice daily doses of 100 mgm for 14 days, (3) 25 mgm twice daily for 14 days, this was tried in one case only and was found to be as effective as (2) above It is stated that "with the dosage mentioned above and the method used", temperatures became normal in 1 to 3 days and parasitaemia disappeared in 2 to 4 days There were no relapses during the patients' stay in hospital (7 to 35 days) No toxic effects were noted with these dosages Gametocytes were unaffected

FITZHUGH O G NELSON, A A & HOLLAND, Oma L **The Chronic Oral Toxicity of Chloroquine** *J Pharm & Exper Therap* 1948, June, v 93, No 2 147-52 1 chart

Chloroquine (SN 7618), which is 7-chloro-4-(4-diethylamino-1-methylbutyl-amino) quinoline was synthesized during the last war in America and proved an active antimalarial agent A report on its properties was made by LOEB [this *Bulletin* 1946 v 43, 708] and WISELOGLE [Survey of Anti-malarial Drugs 1941-1945, *ibid*, 1947, v 44, 1106] According to MOST *et al* [*ibid*, 1946, v 43 1011] it appeared to be more active than quinine and quinacrine (atebrin m. pacrine) in *P. vivax* infections under the conditions of test The present report in which experiments lasted 2 years compares the earlier results of the authors [*ibid*, 1946, v 43, 525] on the chronic oral toxicity of quinacrine with those obtained with the newer drug Groups of 10 male and 10 female rats 21 days old were given six diets containing from 100 to 1000 ppm chloroquine, to which they had free access in individual cages under controlled conditions of temperature and humidity

The growth of rats on the diet with 100 and 200 p.p.m. did not differ from controls. With 400 p.p.m. there was early retardation of growth, but at the end of one year the variation from controls was not significant. Higher doses reduced growth and caused death within a year. Leucocytosis, chiefly neutrophilic, resulted from continued administration of medium or high doses. Haemoglobin and red cell numbers were also increased by the latter.

The principal lesions encountered were a focal necrosis of striated muscle especially cardiac and necrosis and fibrosis of the central lobules of the liver. There was a marked distinction in frequency and severity of the lesions between 400 and 800 p.p.m. dose levels. At 200 p.p.m. or below lesions were slight. From calculation it appeared that the dosage of chloroquine which would produce toxic effects in rats is higher than either the therapeutic or prophylactic dosage recommended for man. The general inference of the authors was that chloroquine is slightly less toxic than quinacrine for rats. The pathological lesions caused by these drugs showed similarities.

STRAUS, B. & GRAYSON, J. Evaluation of Pentaquine as a Cure of Relapsing Vivax Malaria. A Controlled Study of Ninety Five Cases. *Bull. New York Acad. Med.* 1948, June v. 24 No. 6, 393-6.

This study was designed to test the efficacy of pentaquine combined with quinine in the therapy of naturally acquired *P. vivax* infections in man. The patients were v-servicemen in the Veteran Administration Hospital, Bronx, New York and totalled 83. 84 of them had served in the south-west Pacific theatre. All had *P. vivax* infections. Controls were made with chloroquine (SN 7618) because it is highly effective in treatment of the attack but has little if any effect on relapses. It was given as the diphosphate in a dosage of 0.6 gm. of base followed in six hours by 0.3 gm. and 0.3 gm. on the 2nd and 3rd days. Pentaquine was given as the monophosphate in a daily dose of 30 mgm. base (10 mgm. every 8 hours) with 0.6 gm. of quinine sulphate for 14 days. The dosage of pentaquine is half the recommended daily dose of 60 mgm. of base. This reduced dose was used to decrease toxicity and was regarded as feasible as it was likely that most of the men would have had some degree of immunity.

The study began in January 1947 with 48 patients in the chloroquine group and 49 in the pentaquine-quinine group. Follow up, which varies from 1 week to 14 months, will continue for at least a year. At present 83 per cent. of patients have been followed up for more than 4 months. To date none of the patients in the pentaquine group has relapsed. 14 of the chloroquine group have relapsed (17 from the S.W. Pacific). One patient had three relapses and two had two relapses.

Toxic manifestations in the pentaquine-quinine group were mostly insignificant though some did occur in 75 per cent. of patients. In no case was it necessary to discontinue pentaquine though quinine had to be discontinued in one case. Nausea, anorexia and occasionally vomiting, occurred commonly in the first 4 days and mild abdominal pain after the first week. Tinnitus, dizziness and headache were not uncommon. Six patients showed a decrease of 1 million red blood cells or less per cmm. but no frank haemolytic reactions were seen. Fever (99.6°-100.4 F) lasting for one day occurred in 7 patients from the 7th to the 11th day. It is suggested that many of the toxic manifestations were probably due to quinine.

The results so far suggest that one-half of the previously recommended dosage of pentaquine eradicates relapsing *vivax* malaria.

WRIGHT C I & SABINE, Jean C, with technical assistance of Anne H WRIGHT
Cholinesterases of Human Erythrocytes and Plasma and their Inhibition
by Antimalarial Drugs J Pharm & Exper Therap 1948, June, v 93,
No 2, 230-39, 5 figs [20 refs]

The study now reported forms part of a wider investigation undertaken to find if any relationship exists between antimalarial activity and toxicity of chemical compounds and their inhibitory action on cholinesterase. The enzyme present in red cells and plasma was used, as qualitative differences have been ascribed to them. The antimalarial drugs employed were quinine, quinidine, plasmoquine, quinaquine [atebrin, mepacrine], chloroquine and paludrine. Their inhibitory power was estimated manometrically by their effect on hydrolysis of acetylcholine. Suitable dilutions of the enzyme preparations were in the reaction flask and acetylcholine was added from the sidearm. Chloroquine and quinaquine inhibited the enzymes from both sources about equally, while the remaining four drugs were less effective against that from red cells. There was no correlation between inhibitory action on cholinesterase and antimalarial activity or toxicity J D Fulton

WATERHOUSE, D F, ATHERTON, D O Spray Tests against Adult Mosquitoes
1 Laboratory Spray Tests with Culex (Culex fatigans) Adults [WATER-
HOUSE] Commonwealth of Australia Council for Sci & Indust Res Bull
No 219, pp 1-27, 3 figs [11 refs] 2 Spray Tests with Anopheline
(Anopheles punctulatus farauti) Adults [WATERHOUSE & ATHERTON] Ibid,
pp 29-40, 2 pls

1 The first paper deals with initial exploratory tests of sprays against *Culex fatigans* under standardized laboratory conditions in Canberra, during 1942 and 1943. They were designed to provide information on the minimum effective concentration of pyrethrins and also to evaluate the effectiveness of Lethane, Thanite, DDT and other synthetic materials.

Eggs of *C fatigans* were collected in the field and reared to adult stage in the laboratory at $80 \pm 1^\circ\text{F}$ (26 to 27°C) and 70 ± 2 per cent relative humidity. The adults were kept in cages for four to six days after emergence and fed on fruit, not blood. The tests were made in a Peet-Grady chamber with the standard spray gun and a 2 ml dosage (one-sixth of the standard dose for flies) equivalent to 1 fl oz per 3,000 cu ft. The spray was applied at 12.5 lb air pressure and the mosquitoes remained exposed to the mist for ten minutes. They were then all collected and after the percentage knockdown was calculated, were transferred to a clean cage with fresh apple and left for twenty-four hours.

About 350 tests were made on more than 30,000 mosquitoes. The results show that a spray of 0.14 per cent pyrethrins gave 99.3 per cent knockdown and kill. DDT and Thanite also showed promise. A spray containing 1.0 per cent DDT gave 94 per cent mortality but only 55 per cent knockdown, the addition of 0.1 per cent DDT to a 0.01 per cent pyrethrins spray increased mortality by 16 per cent. A 3.5 per cent Thanite spray was about equal in

effectiveness to the 0.14 per cent. pyrethrins spray but 0.5 per cent. Thanite added to a 0.01 per cent. pyrethrins spray resulted in a lowering of both knockdown and mortality. Lethane was neither highly toxic to the mosquitoes nor did it serve any useful purpose when added to a pyrethrum spray. Other synergists had little or no effect on pyrethrum sprays used against *C. fatigans*.

2. The second series of tests was an extension of the laboratory experiment recorded in the first paper. They were made in tents or native huts with caged wild-caught females of *Anopheles punctulatus farauti* at Lalapeli in New Guinea in September 1943. Dosages of 1 fl. oz. per 2,100 cu. ft. and 1 fl. oz. per 3,000 cu. ft. were atomized by pressure sprayer and by hand spray gun. An interval of ten minutes was allowed and the percentage knockdown noted. The tent was aired for twenty minutes and mortality rates were recorded after 1.5 and 18-20 hours. Temperature varied between 82 and 90 F. (27.5 and 32 C.) and relative humidity between 68 and 92 per cent. A total of 10,800 female mosquitoes were used in 236 experiments in which 32 sprays were tested.

The results agree (except for Thanite sprays) with the laboratory tests on *C. fatigans* described in the first paper. The reason was probably the greater fumigating effect in the Pect-Grady chamber.

For sprays containing pyrethrins alone it would not be desirable to use solutions weaker than 0.07 per cent. pyrethrins which gave 98.5 per cent. knockdown and 99 per cent. kill (concentrations above this gave complete kill and knockdown). A 0.5 per cent. DDT spray gave 97 per cent. mortality but only 33 per cent. knockdown; however the addition of 0.03 per cent. pyrethrins improved the knockdown to 98 per cent. Five per cent. Thanite did not give sufficiently high kill, but a 3.5 per cent. Thanite-0.5 per cent. DDT mixture gave good knockdown and high mortality. The use of such an unpleasant spray would only be justified if pyrethrins were not available.

In practice these sprays gave freedom from attack by *A. farauti* for about 6 to 8 minutes and they had no persistent lethal effect but the application in one tent, of DDT at the rate of 50 mgm. per cu. ft. freed it of resting anophelines for some weeks.

The evidence provided by the tests in the second paper confirmed the decision of the Australian Army authorities not to vary the 0.14 per cent. pyrethrins spray adopted provisionally as a result of the test reported in the first paper and not to include a synergist. This was used until the advent of DDT in the last year of the war in sufficient quantity to reinforce the spray and convert it into an all-purpose one.

BRITISH GUIANA. Report of the Honorary Government Malariaologist for the Year 1947. GIGLIOLI, G. Mosquito Control Operations by Residual D.D.T. in British Guiana. Filariasis Survey of the Coastlands. 14 mimeographed pp. 1 map.

In January 1947 the Yellow Fever Service and the Malaria Research Unit of British Guiana were combined into a Mosquito Unit of Service. The DDT residual spraying of houses was made compulsory in localities declared DDT control areas by the Director of Medical Supplies.

Meteorological and population figures are listed and the organization of the spraying unit is described. Malaria is either endemic or sub-pendemic in the coastlands exterior and in bush and peripheries of towns. In the interior it is widely and by endemic in most communities. The vector is *Anopheles farauti*, *A. aquas*, and *A. tritaeniorhynchus* were not proved to be transmitters of malaria but they are potential vectors and possibly maintain small proportions of malarial parasites in the north-west where *A. aquas* is proved to be a carrier. These species with *A. tritaeniorhynchus* are exophilic and non-domestic and are thus not affected by DDT house spraying.

The aim is to treat all buildings in control areas with 150 mgm DDT per square foot at intervals of eight months, which may later be extended to 10 or even 12 months. In 1947, 32,458 buildings in the coastal area were treated, involving 262,832 persons or 89 per cent of the coastal population and 70 per cent of the total population. Spraying in the remaining parts is now proceeding. In the interior, considerable spraying was done by the mining companies.

Immediately after treatment, adults of *A. darlingi* disappear and larvae disappear two or three weeks later. It is claimed that in these areas *A. darlingi* has now been eradicated. Figures are given to show the reduction in spleen rates and the slower reduction in the parasite rates.

A survey of filariasis is proceeding and figures are given for 1946-47 showing the distribution by race, sex and age and the degree of infestation, etc. It is expected that the effect of the DDT sprayings on the incidence of filariasis will be much slower in its development than it is on the incidence of malaria.

A monograph on mosquito-borne diseases in British Guiana and on three years of investigation on their control by DDT is being prepared and will soon be available.

The report concludes with a list of publications issued during the year

PRATT, H D **Relation of Plants to Malaria Control in Puerto Rico** *Supplement No 200 to Pub Health Rep* Wash 1947, Dec, 38 pp, 3 charts & 10 figs [11 refs]

This paper describes plant communities in Porto Rico and their relations to anopheline production. Various plant associations are described and control methods appropriate to them.

Examples are, the control of *A. albimanus*, breeding in mangrove swamps by drainage, dusting and "salting up" from sea-level canals, and the drainage of flats and oiling of temporary pools where *Batis maritima* and *Sesuvium portu-lacastrum* dominate and lead to the breeding of *Aedes taeniorhynchus*, *Aedes sollicitans* and *Psorophora ferox* and *P. pygmaea*. In coastal swamps where *Typha angustifolia* and *Phragmites* dominate, *albimanus* breeds only at the sunlit margins, and drainage and dusting with Paris green has been successful. For grasslands and pasture, where temporary pools in small depressions or hoofmarks may lead to heavy breeding the plant associations are dealt with in some detail. It is pointed out that tall grasses may render larvicidal methods difficult and control by drainage is recommended. Sugar-cane fields present a special problem. In newly cut fields there is little breeding, but as the trash sinks into the irrigation ditches and the water surface becomes sunlit, and especially when the ditches are reflooded after fresh planting, then *A. albimanus* increases until after the canes reach a metre in height, when *A. grabhami* gradually replaces *albimanus*. When the canes are at full height, *A. vestitipennis* may be the only species present.

Plants which tend to inhibit anopheles production are listed, such as duckweed, *Azolla*, *Pistia* and other species which make floating mats. *Ceratophyllum demersum*, on the other hand, produces mats beneath the surface and so protects anopheles larvae from natural enemies, and, in Porto Rico this species is particularly associated with *albimanus*. Other plants of similar habit (*Chara Utricularia*) have the same effect.

The use of the cable saw for clearing subaquatic vegetation, plants useful in bank sodding and the methods used for eliminating *albimanus* breeding in flotage in sheltered water behind sandbars are also described. Finally, a key, based on simple vegetation characteristics, to the 138 important plant species associated with anopheles in Porto Rico is given.
C G Johnson

effectiveness to the 0.14 per cent. pyrethrins spray but 2.5 per cent. Thanite added to a 0.01 per cent. pyrethrins spray resulted in a lowering of both knockdown and mortality. Lethane was neither highly toxic to the mosquitoes nor did it serve any useful purpose when added to a pyrethrum spray. Other synergists had little or no effect on pyrethrum sprays used against *C. fatigans*.

2. The second series of tests was an extension of the laboratory experiments recorded in the first paper. They were made in tents or native huts with caged wild-caught females of *Anopheles punctulatus* and at Lalapagi in New Guinea in September 1943. Dosages of 1 fl. oz. per 2,100 cu. ft. and 1 fl. oz. per 3,000 cu. ft. were atomized by pressure sprayer and by hand spray gun. An exposure of ten minutes was allowed and the percentage knockdown noted. The tent was aired for twenty minutes and mortality rates were recorded after 1.5 and 18-20 hours. Temperature varied between 82 and 90 F. (27.5 and 3° C.) and relative humidity between 68 and 92 per cent. A total of 10 dead female mosquitoes were used in 236 experiments in which 32 sprays were tested.

The results agree (except for Thanite sprays) with the laboratory tests on *C. fatigans* described in the first paper. The reason was probably the greater fumigating effect in the Pet-Grady chamber.

For sprays containing pyrethrins alone it would not be desirable to use solutions weaker than 0.07 per cent. pyrethrins which gave 94.5 per cent. knockdown and 99 per cent. kill (concentrations above this gave complete kill and knockdown). A 0.5 per cent. DDT spray gave 97 per cent. mortality but only 33 per cent. knockdown; however the addition of 0.03 per cent. pyrethrins improved the knockdown to 98 per cent. Five per cent. Thanite did not give sufficiently high kill but a 3.5 per cent. Thanite + 0.5 per cent. DDT mixture gave good knockdown and high mortality. The use of such an unpleasant spray would only be justified if pyrethrins were not available.

In practice these sprays gave freedom from attack by *A. p. fatigans* for about five minutes and they had no persistent lethal effect but the application in a tent of DDT at the rate of 50 mgm. per sq. ft. freed it of resting anophelines for some weeks.

The evidence provided by the tests in the second paper confirmed the decision of the Australian Army authorities not to vary the 0.14 per cent. pyrethrins spray adopted provisionally as a result of the tests reported in the previous paper and not to include synergist. This was used until the advent of DDT in the last year of the war in sufficient quantity to reinforce the spray and convert it into an all purpose one.

II. 5. Lesson

BRITISH GUIANA. Report of the Honorary Government Malarialogist for the Year 1947 (GIGLIOLI G. Mosquito Control Operations by Residual D.D.T. in British Guiana. Filariasis Survey of the Coastlands. 14 mimeographed pp. 1 map.

In January 1947 the Yellow Fever Service and the Malaria Research Unit of British Guiana were combined into Mosquito Control Service. The DDT residual spraying of houses was made compulsory in localities declared DDT control areas by the Director of Medical Supplies.

Meteorological and population figures are listed and the seasonal incidence of spraying units is described. Malaria is either endemic or hyperendemic in the coastlands, estuaries and in suburbs and peripheries of towns. In the interior it is widespread and hyperendemic in most communities. The vector is *Anopheles darlingi* in the west and *A. tritaeniorhynchus* in the east. They are not proved to be transmitters of malaria, but they are potential vectors and possibly maintain small proportions of local malaria in the north west where *A. gambiae* is reported to be a carrier. These people with *A. tritaeniorhynchus* as vector are not domestic and are thus not affected by DDT house spraying.

RODMAN J. Contribution à l'étude des Plasmodiums des anthropokles africains. Transmission du *Plasmodium malariae* de l'homme au chimpanzé. [Transmission of Human *Plasmodium malariae* to the Chimpanzee.] *Ann. Soc. Belg. de Méd. Trop.* 1948, Mar 31 v 28 No. 1 39-49

The author had previously shown that the quartan malaria parasite (*P. rodhami*) of chimpanzees was transmissible to man (this *Bulletin* 1943, v 40 438) giving rise to an infection indistinguishable from that caused by *P. malariae*. He now reports the results of the inoculation of human *P. malariae* into chimpanzees. The first attempts were negative but in 1947 three transmission of a strain obtained from Mr P. G. Shute of Horton were successful. 10-15 cc of defibrinated blood containing numerous *P. malariae* parasites were inoculated intravenously into young chimpanzees. The parasites were subsequently found for varying periods in the peripheral blood, augmenting to a crisis when as many as 7000 per cmm. were found in one case. The animals showed no ill-effects from the disease. The infection disappeared spontaneously in one of the chimpanzees, but still continued in a very sparse form in the remaining two. Blood from one chimpanzee at the height of the infection was put back into a human being and gave rise to a typical attack of quartan malaria. The chimpanzee must therefore be regarded as a reservoir of *P. malariae* in Central Africa.

[It is now more than ever certain as a result of these experiments that *P. rodhami* should be regarded as being a synonym of *P. malariae*.]

RIGDON R. H. A Consideration of the Use of Blood and Oxygen as Supportive Therapy in the Treatment of Malaria. *Am. J. Cl. Path.* 1948, June v 18 No 6, 485-90 3 figs. 11 refs.]

In various publications since 1941 (this *Bulletin* 1943 v 40 118, 430 1946, v 43 309 630 1947 44 503 883 1035) it has been demonstrated both experimentally and clinically that in acute malaria infections anaemia results from parasitic destruction of the red cells and from an acidosis which further decreases their oxygen-carrying capacity. Monkeys infected with *P. knowlesi* at different stages of the infection were treated with oxygen, with immediate and spectacular improvement in their general condition. This improvement lasted while the animals were in the oxygen chamber; on withdrawal from the oxygen chamber the monkeys rapidly collapsed. In other cases, entry of the animal into a chamber containing approximately a 40 per cent concentration of oxygen together with quinine treatment was found beneficial; the oxygen served as a supportive measure until the quinine destroyed the parasites. Yet again, combined quinine treatment, transfusions of human blood, and entry into an oxygen chamber greatly prolonged the lives of monkeys moribund from *P. knowlesi* infections.

The blood transfusion and oxygen treatment of malaria is based on sound physiological principles. Capillary occlusion with prethoracic haemorrhages is found in various organs in *P. falciparum* infection; this is due to a stagnant anaemia with increased permeability of the capillaries which leak their fluid

content into the surrounding tissues, so producing haemo-concentration. Why these lesions should occur in one case in the brain and in another in the lungs or the heart is not known. Nicotinic acid causes dilatation of the cerebral capillaries, and "aids in restoration of respiratory systems", it has been used both alone and in conjunction with oxygen in the treatment of *P. falciparum* infections in man, with rapid relief of symptoms [this *Bulletin*, 1944, v 41, 536, 1947, v 44, 495]. Transfusions, oxygen, and nicotinic acid are only adjuvants to the specific drug treatment of malaria, but they may support the patient until this has time to act.

VINCKE, I H & LIPS, M. Un nouveau plasmodium d'un rongeur sauvage du Congo, *Plasmodium berghei* n sp [*Plasmodium berghei*, a New *Plasmodium* of a Wild Rodent in the Belgian Congo] *Ann Soc Belge de Méd Trop* 1948, Mar 31, v 28, No 1, 97-104, 14 coloured figs on 1 pl

A new *Plasmodium* (*P. berghei*) from Congo tree rats is described. The rats belonged to at least 5 species, including *Thomomys surdaster*. 14 out of 93 rats showed parasites in the blood. The infection can be transferred with ease to white mice and to rats (*R. r. frugivorus* and *alexandrinus*), in which animals it causes a heavy parasitaemia followed by death between the 11th and 15th days. In inoculated wild rats, the infection as a rule is less severe. There is enormous enlargement of the spleen and liver, which are heavily pigmented. The blood of infected animals shows ring forms usually with one chromatin dot, followed by schizogonic forms. When mature, these divide into 6 to 20 merozoites surrounding a central mass of black pigment. Macro- and microgametocytes are produced, these have fine black pigment and measure 7 to 8 μ in diameter. The most characteristic features of the parasites are two—the frequency with which multiple infections of the erythrocyte occur and the gross enlargement of this cell. Sometimes six rings are found in a single cell and the cytoplasmic masses are apparently continuous. The absence of pigment is about the only feature which enables such forms to be distinguished from schizonts. The diameter of the rat's corpuscles is normally between 5 and 6.5 μ , infected corpuscles enlarge to 10.6 μ . Stippling does not occur.

The insect vector of *P. berghei* is most probably *Anopheles duren*, common anophelines (e.g., *A. gambiae*) of the region failed to transmit it. Before the discovery of this parasite, *A. duren* had often been found infected with sporozoites in the salivary glands (7 per cent rates). It had been found in large numbers gorged with blood, in the tree canopy of the forest near Elisabethville. The blood was mammalian but rarely or never human, dog, cat or antelope. The authors therefore looked for an animal host prevalent in the forest canopy and they incriminated the tree rats, a successful climax to a very intelligent piece of field work. During the 1947-1948 season, *A. duren* failed to show infections in the glands (out of 1,203 examined) and so far sporozoite transmission from this mosquito to the rat has not been made. Parasites resembling *P. berghei* have, however, been found in the gut of wild-caught *A. duren*, and in one case the contents of the gut, when inoculated into a white mouse gave rise to a fatal infection due to a parasite apparently identical with *P. berghei*.

RIGDON, R H & ROSTORFER, H H. Observations on the Anemia in Ducks Infected with *P. lophurae* *Blood* 1947, May, v 2, No 3, 244-55, 5 figs [15 refs]

This paper is written in a confused and, it must be confessed, somewhat confusing manner. Thus, at the beginning of the section "Experimental",

reference is made to figure 12 demonstrating the parasitaemia and anaemia in a typical malarial infection in a fatal case. The height of parasitaemia is shown in the figure as occurring on the 13th day yet a few lines below the words quoted above comes the statement 'In these ducks the peak of the parasitaemia is reached on the 15th day.'

The author's conclusions would appear to be that the anaemia caused by *P. falciparum* in ducks is due to destruction of mature erythrocytes and the replacement of the latter by erythroblasts which are poor absorbers of oxygen. The rapid diminution in the number of parasitized cells after the peak of the infection is considered to be due to the fact that the erythroblasts as such are unsuitable to the needs of the parasite and do not become parasitized.

CINGRICH W. D. Duration of Immunity to Malaria (*Plasmodium culicivorum*) in the Canary. *J. National Malaria Soc.* 1948, June v 7 No. 2 109-17 8 figs.

This account of the duration of immunity to *Plasmodium culicivorum* in the canary is based on the reactions of canaries, cured of blood-induced infections by anti-malarial drugs, to inoculations of the homologous strain of the parasite.

These inoculations were made at monthly intervals in two series in one of which each bird received 500,000 and in the other 10,000,000 parasites. Controls consisted of (a) birds with latent infections and (b) normal birds.

The conclusions drawn by the author from the experiments were based on three criteria: (a) increasing or decreasing parasitaemia after the first inoculation; (b) the degree of parasitaemia produced; and (c) the duration of the patent parasitaemia.

These conclusions may be summarized by stating that the birds showed a progressive decline in their acquired immunity from the first month after cure until the sixth month with a total extinction of immunity after eight months.

BLACKWATER FEVER

TISSECTL, J. La fièvre hémoglobinoque en 1942 dans les troupes stationnées au Soudan, en Guinée et Côte d'Ivoire. *Blackwater Fever in 1942 in Troops Stationed in French Sudan, Guinea and Ivory Coast.* *Bull. Soc. Path. Exot.* 1948 v 41 No. 3 4 173-8

In 1942 there were 98 cases of blackwater fever in a population of about 4,000 Europeans in Central French West Africa. There were no cases among an indigenous population in the same region which numbered about 35,000. Most cases occurred in the second half of the year which was the epidemic season of malaria and most of those affected had some form of active employment. Blackwater fever was common among those who were in the habit of treating themselves with quinine during an attack of malaria. In 1942, quinine was used as a suppressant during the first half of the year and prophylaxis during the second half. Quinine was used throughout the year in small isolated posts. Another drug was however apparently taken regularly in two districts the maximum incidence of blackwater fever was recorded during the first half of the year when quinine was being taken. In the second half

of the year when prémaline was distributed the number of cases was reduced, especially where the drug was correctly taken. Thus, in Camayenne near Goléah and Konakry, malaria was as severe as in neighbouring areas, but in 70 Europeans there was not one case of blackwater fever. In this district prémaline was taken correctly, while in Goléah, where quinine was being administered, two Europeans out of five developed blackwater fever. Out of a total of 37 deaths among Europeans, 28 were due to it. Classical treatment was not very effective, the death rate ranging from 15 to 35 per cent. Attempts to prevent the development of blackwater fever included monthly systematic splenic examinations of all Europeans. All those with palpable spleens were given the following treatment—quinine 1 gm daily for 2 days, quinine 300 mgm daily for 5 days. The taking of suppressive drugs daily was insisted upon and maintenance of drug suppression was ordered for 15 days to three months after the subject left the endemic area.

B G Macgrath

LEFROU, G. Considérations sur l'étiologie de la fièvre bilieuse hémoglobinurique à propos de 123 cas observées au Soudan. [Observations on the Aetiology of Blackwater Fever, arising out of 123 Cases in French Sudan. *Bull Soc Path Exot* 1948, v 41, Nos 3/4, 176-87]

This is an account of the results of an enquiry which originated as a result of the unusually high incidence of blackwater fever in French Sudan during 1942 and 1943. Most of the cases referred to were treated in hospital at Bamako and this study, together with previous records, covers 82 patients from 1943 to 1946 including 72 males, 10 females, 6 were children from 2 to 10 years of age. The incidence of blackwater fever was seasonal, the maximum number of cases occurring during the warm rainy period, particularly in September when *P. falciparum* malaria was most prevalent. Cases were very rare during the hot dry season. Of 100 cases investigated, 20 had lived in the district for one year, 39 for two, 22 for three and 19 for four or more years. The author concludes that there is no obvious relation between the length of stay and the onset of blackwater fever. There were 8 subjects who developed blackwater fever within the first six months of their tour, all of whom had lived previously in Africa. Three cases occurred among new arrivals in Africa within the first year. The severity of the attack increased with the length of stay, the mortality after three or four years being considerably higher than that after one or two years. Over the period discussed there were only six recorded cases of blackwater fever in Africans.

Since the introduction of controlled suppressive antimalarial drug treatment blackwater fever has become rare in French Sudan. The abrupt rise in incidence in 1942 was probably related to irregular quinnization, resulting from difficulty in obtaining supplies in that year. The author emphasizes the danger of prescribing or taking quinine indiscriminately and irregularly. Blackwater fever developed in some cases during the administration of quinine either orally or parenterally for the treatment of a current attack of malaria. It was never observed in those taking regular quinine prophylactically. Haemoglobinuria sometimes appeared in persons suffering from malaria who have never taken quinine, e.g. in members of the indigenous population. The author includes chills, and emotional disturbances as predisposing factors.

MEYER H & XAVIER DE OLIVEIRA, M Cultivation of *Trypanosoma cruzi* in Tissue Cultures a Four-Year Study Parasitology 1948, July, v 39, Nos 1/2, 91-4, 17 figs on 2 pls

Trypanosoma cruzi has been cultivated by the tissue culture technique by various workers, but the present account describes what is probably the most comprehensive study of *T. cruzi* on these lines The method employed was Carrel's hanging drop technique

Several interesting observations are made among them the curious fact that although the organism was easily maintained in tissue culture in chick embryo material over a period of more than two years yet living chicks could not be infected with the cultures. Other observations were that the entire cycle—trypanosome, leishmania form crithidia and back to trypanosome—took place in one cell and the number of trypanosomes produced was proportional to the size of the host cell. No division of adult trypanosomes was observed nor any indication of sexually differentiated forms. [The paper is evidently a condensation of a great deal of original observation which would repay fuller description.]

H. E. S. A. 2

LEISHMANIASIS

GIRAUD P. BERNARD R. & BERGIER, P. Chronique du kala-azar à Marseille (A Review of Kala Azar in Marseilles.) *Bull. et Mem. Soc. Méd. Hôp. de Paris* 1947 Nos. 3/4 61-2.

In 16 years up to 1939 the authors recorded 165 cases of leishmaniasis in the Marseilles area. In the 8 years 1939-1946 they have found 73 more giving a total of 238. The average number of cases annually for the two periods was thus about the same.

The yearly incidence for the years 1939-1946 is given in a table and shows a sharp drop in 1942-1944 which years only a craged 3 cases. This was followed by a brisk rise in 1945-1946. The authors have not entirely satisfied themselves as to the exact cause of this change. No doubt the dry years 1943 and 1944 were unfavourable to the breeding of the insect vectors and the rainy years 1945 and 1946 (when there were 16 and 17 cases) were favourable to such breeding. The disappearance of many dogs during the wartime period of food shortage would not be sufficient to explain the change in incidence. The authors, however, noted a comparable situation in the endemic region observed between 1930 and 1935 when there was a similar variation with a maximum of 4 cases in 1932.

Over half the patients were under 3 years of age and the incidence fell rapidly after 4 years. Three cases were in infants under 10 months and only one in an adolescent and two in adults. Infection occurred regularly in the suburbs and country districts. Two cases originated in Corsica.

The topographical distribution and incidence in dogs corresponded closely with that in man over the same period. (Land juncture (shoulder) was simple and reliable in dogs see also this *Bulletin* 1948 45 883).

The authors believe an epidemiological ground that the local endemic is essentially a disease of dogs accidentally transmitted to man by tick rather than by *Phlebotomus* and that in general it is endemic in the French Mediterranean area is constant and stable. It added that two children with kala azar also had histoplasmosis. H. J. O. D. B. *Act. Guy.*

RACHMILEWITZ M. BRAUN, A. & LEVINE, A. Hematologic Observations in a Case of Kala-Azar. *Bk. J.* 1947 July. N. 4 381-5 1 illus. 1 ref.

The hematologic findings in a case of kala azar under the influence of specific treatment are described. The type of the anemia the leucopenia, bone marrow changes (increased proliferation in spleen before treatment, and the subsequent changes following treatment) strongly suggest increased red cell destruction most probably by phagocytosis as the cause of the anemia.

DE AZEVEDO, J F, TEIXEIRA, A W G & COITO, A de M F Sobre a infestação por leishmanias nos cães de Lisboa [Leishmania Infection in Stray Dogs in Lisbon] *An Inst Med Trop* Lisbon 1947, Dec, v 4, 99-106

The English summary appended to the paper is as follows —

"As a complement to the studies carried out in the Institute of Tropical Medicine on the epidemiology of the kala-azar, the authors have determined the rate of infestation by leishmaniae in vagrant dogs of Lisbon

"For this purpose, from 1945 to 1947, they searched for leishmaniae directly in spleen, as well as in liver smears of those animals, by culture of these organs (medium NNN) and in bone marrow and nasal mucus smears

"Out of 137 dogs examined, 9 have been found infected, which gives an infection rate of 6.5 per cent, a percentage considerably higher as compared with those of 3.6 and 2.08 per cent found by other investigators also in dogs of Lisbon in the periods of 1910-1912 and 1936-1938 respectively. In one of the dogs leishmaniae have been found in the nasal mucus

"They also observed that the largest proportion of infected animals was found among the oldest dogs and that the infection rate in the females was larger than that of the males"

SMITH, R E, STEELE, J M, EAKIN, R E & COWIE, D B The Tissue Distribution of Radioantimony Inhaled as Stibine *J Lab & Clin Med* 1948, May, v 33, No 5, 635-43, 7 figs

BRADY *et al* [this *Bulletin*, 1945, v 42, 747] studied the fate of radioactive trivalent antimony in dogs after intravenous injection. The inhalation of stibine (SbH_3), a gaseous trivalent compound of antimony, was shown by the present authors to cause reduction in the level of parasitaemia of chickens infected with *P. gallinaceum*. This substance containing the metal in radioactive form has now been used to determine the concentration of Sb in the blood and tissues of normal and infected chickens as well as in guinea-pigs at various time intervals after administration.

The antimony isotopes were prepared by bombardment in the cyclotron and the two forms produced with a half life period of 2.8 and 60 days respectively were used as a mixture for the production of stibine by the action of HCl on the fusion product with magnesium. The animals were exposed to various concentrations in a special chamber for different periods and on removal were bled prior to removal of tissues for estimation of antimony. The radioactivity of samples was measured by means of a beta ray counter under standard conditions and the amount of Sb determined with reference to standards. The concentration of stibine in the chamber was approximately 25 parts per million and the time of exposure about 50 minutes.

Haemolysis of red blood cells occurred in some cases. The results obtained with chickens heavily infected with *P. gallinaceum* were not significantly different from those with controls. The concentration of Sb in the blood stream fell off gradually but more rapidly in guinea-pigs than in chickens. At first there was some localization in red cells but the excess of metal over that in plasma was reduced with time. The concentration in most tissues approximated to those in blood, but in liver and spleen there was a maximum level about 1 hour after treatment, and after four hours the level was higher in liver, spleen and kidney than in whole blood. Antimony appeared to be eliminated at a greater rate by the guinea-pig than by the chicken.

RABLOWITZ, Esther, USCINER, M. & GROSSOWITZ, N. Cultivation of *Rickettsia prowazekii* in Dead Chick Embryos. *Proc Soc Exper Biol. & Med.* 1948, Apr., v 67 No. 4 469-70

Living cells were still present in chick embryos 18 days after the latter had been killed, on the third day of development, by chilling at 4°C. for 4 hours and then kept even at a temperature of 37°C.

Rich cultures of rickettsiae were found after 14 days of cultivation in embryonated eggs killed by chilling and inoculated within about seven days. Storage was at room temperature.

Successful cultivation was obtained with rickettsial suspensions containing too few organisms to yield cultures when the usual technique was adopted. The special advantage of the method is that the killed embryos can be stored "for some time" and then used like ordinary culture media. The eggs can be inoculated in the field and transported to the laboratory without the special precautions that are needed when living embryos are employed.

CLARKE, Delphine H. & FOX, J. P. The Phenomenon of *in vitro* Hemolysis produced by the Rickettsiae of Typhus Fever with a Note on the Mechanism of Rickettsial Toxicity in Mice. *J. Exp. Med.* 1948, July 1 v 88, No. 1 3-41 [12 refs.]

Suspensions containing sufficient numbers of *Rickettsia mooseri* or *R. prowazekii* especially when prepared from yolk-sac cultures were found to cause haemolysis *in vitro* of red blood cells of rabbits and sheep but not of mice, cotton rats and guinea-pigs. Suspensions of *R. orientalis* did not haemolyse rabbit cells.

The haemolysis was closely associated with the bodies of living rickettsiae being present in the sediment obtained by high-speed centrifugation but not in the supernatant fluid. It was destroyed by formal (0.5 per cent) and by heating to 56°C. for one hour. Its activity in suspensions was parallel with the toxicity for mice and the infectivity for cotton rats of the suspensions.

It is thought likely that the degree of haemolytic activity may turn out to be a rapidly observable though only roughly quantitative index of the infectivity of suspensions. Homologous antisera inhibit the haemolytic action which therefore may form the basis of a useful serological test having the special feature of depending on a property of living rickettsiae. The haemolytic factor may possibly be identical with the rickettsial toxin which is known to cause early death in experimental mice.

SANDOR, G., GIROUD, P. & SKRONSZ, C. Mlle. Etudes des anticorps anti-rickettsiales du serum de lapin. [Study of Rickettsial Antibodies in Rabbit Serum.] *J. de l'Inst. Pasteur* 1948 June 74 N. 8 518.

In a previous note (this Bulletin 1948, 45) the authors discussed the identity of the antibodies produced in rickettsial antiserum and they now present the first results of the application of their technique in demonstrating the antibodies in rabbit serum.

As in the case of normal rabbit serum, efficient precipitate cannot be extracted by simple dialysis when distilled water is used. Any rat of Indian origin is preferred for only 2 or 3 days. Anticoagulant is platinum about pH 5.5 on the other hand makes it possible to obtain abundant precipitate from dialysed serum diluted one in four. This precipitate accounts for an α_2 value of 0.8.

per cent of the serum proteins and can be separated into an insoluble and a soluble protein fraction in about equal parts, in the presence of a dilute phosphate buffer (N/100) at about pH 6 these are euglobulin II B and II A

The insoluble fraction disperses with difficulty and only in weakly alkaline medium, producing a markedly opalescent suspension. It represents a lipoprotein complex containing about 40 per cent of lipids consisting entirely of neutral fats. This fraction is devoid of any agglutinating power against rickettsiae.

The soluble protein fraction contains only a small percentage of lipids and gives a completely clear solution. It often accounts for all the agglutinating activity, but a small but variable proportion of this is also present sometimes in the pseudoglobulins.

In rabbit anti-ovalbumin serum or horse antiglobulin serum there is a euglobulin I which contains a small amount of the specific flocculant factor, but the greater part is to be found in the pseudoglobulins. Common proteins are close to typhus antigens, but viruses differ in this respect. Rickettsiae may be regarded as being comparable with endotoxins or bacterial antigens. Similar results were obtained with STEFANOPOULOS in the case of yellow fever antiserum in the horse.

H J O'D Burke-Gaffney

GAASE A Die Thermostabilität der Agglutinine in der Differentialdiagnose von Fleckfieber und Proteusinfektion [The Thermostability of Agglutinins in the Differential Diagnosis between Typhus Fever and Proteus Infections] *Ztschr f Hyg u Infektionskr* 1948, Apr 1, v 127, Nos 6/8, 730-41, 10 figs [21 refs]

Contrary to the findings of some previous workers, the author has found that the agglutinins against *Proteus OX19* are very variable in their resistance against heating. He tested the sera of 220 typhus patients before and after heating to 56°C for one hour, and found that although heating caused a fall in the Weil-Felix titre in 79.5 per cent there was no change in 13.2 per cent and there was actually a rise in 7.2 per cent. In 68.6 per cent of the cases, the titre after heating remained at a height of 1-400 or over.

In a case of furunculosis due to *Proteus vulgaris*, the patient's serum did not react to *Pr OX19* neither did the serum of any of 10 guinea-pigs which had been immunized against 10 different strains of *Pr vulgaris* although several of these strains were agglutinated by the sera of typhus patients. These findings are regarded as additional evidence of the specificity of the Weil-Felix test for typhus fever.

The agglutinins of the above guinea-pigs against homologous strains of *Proteus* organisms showed a higher average degree of thermostability than was shown by the agglutinins of typhus patients against *Pr OX19*, yet there was a fall in the titre in 13.9 per cent of the cases after heating, so that the thermostability of the agglutinin in the Weil-Felix reaction cannot be regarded as supporting the diagnosis of *Proteus* infection as opposed to that of typhus fever.

BRI-SOT J & MATHIAS R Diagnostic du typhus par réaction de fixation du complément. Etude de divers antigènes. The Diagnosis of Typhus Fever by the Complement-Fixation Reaction. A Study of Various Antigens. *Bull Soc Path Exot* 1948, v 41, Nos 3-4, 112-14.

In a trial of various antigens prepared from typhus vaccines the best results were obtained with a formalized vaccine of the Durand Groun type, preferably less than one year old.

One team consisting of a sanitary inspector and a nurse working 8 to 10 hours a day can do an average of 17 residences giving 107 treatments and examinations without examination the team can do 180 people per day. The treatment costs very little and takes - 25 ounces of 10 per cent. DDT for one person and his bedding, etc., and one ounce of phenyl cellosolve lotion per woman and 0.5 oz. per man.

No toxic effects were observed among the treated persons or the operators.

ESKAY, C. R. & HENRITZ, F. M. Relation of Reported Cases of Typhus Fever to Location, Temperature, and Precipitation. *Pub Health Rep Wash.* 1948 July 18 v. 63 No. 29 941-8 4 figs.

Most of the information contained in this survey of the incidence of murine typhus fever in the U.S.A. is presented in the form of graphs and a map. The total number of cases reported during the period 1913-1944 was nearly 30,000 of which almost 95 per cent. occurred in the southern States.

Owing chiefly to the increasing recognition of the disease 60 per cent. of the cases were reported in the last six years of the above period. [The statement in the body of the paper that 60 per cent. of all the cases occurred during the 31 year period is obviously due to a typographical error.]

The disease is concentrated in the zone between 31° and 33° north latitude especially towards the south of the zone. Fewest cases occurred during the winter and spring months. August, July and September were the months of highest prevalence. The number of cases reported annually increased every year except in 1940 when the number was smaller than in 1909. This departure from the trend is regarded as being due to the exceptionally cold weather experienced in January 1940. There was no significant degree of association between rainfall and rate of incidence. JOHN W. D. M.

CALLOT, J. & VANDERLY, R. Essais d'action enzymatique sur des micro-organismes du groupe des *Rickettsia*. [Studies on the Action of Enzymes on *Rickettsias*.] *C.R. Soc Biol* 1948 Mar. 14, No. 5 6 320-7

The authors have applied a method called enzymatic analysis to the study of the cytological structure of rickettsiae. The method has already been employed in the investigation of bacterial cells by BERT, whose paper on the subject was still in the press at the time of writing.

Rickettsial smears were fixed in absolute alcohol, then treated for various periods up to two and a half hours by solution of one of the two enzymes, ribonuclease and deoxyribonuclease. The smears were washed and stained by Giemsa's stain.

Striking results were obtained by treating the smears with the latter enzyme especially in the case of *Rickettsia psittaci* obtained from the ovaries of infected *Coturnix* f. *psittaci*. After prolonged application the rickettsiae failed to take on the stain.

Smears of *R. mooseri* from infected guinea-pigs were also affected though to a lesser degree but they had not been freshly prepared.

The findings were regarded as supporting the view that rickettsiae are intermediate in structure between bacteria and filterable viruses.

Reference is made to the work of T. W. KILGUS *et al.* *Nature* 1948 Dec 21 917 who has found that the chemical composition of *R. psittaci* intermediate between that of bacteria and viruses. JOHN W. D. M.

PHILIP, C B Tsutsugamushi Disease (Scrub Typhus) in World War II. J
Parasitology 1948, June, v 34, No 3, 169-91, 1 map [30 refs]

This paper consists chiefly of a critical review of the new knowledge of tsutsugamushi disease gained in the course of the Asiatic-Pacific campaign of 1941-1945. Most of the papers referred to by the author have been dealt with in this *Bulletin* and as the article is a summary it does not lend itself to the preparation of an abstract.

A few points of special interest are as follows.—The allied forces escaped several major disasters solely because there did not happen to be any action by the enemy at the times and places of occurrence of large outbreaks of the disease, and it was only because of the prompt and energetic action taken by the allied experts to discover and apply effective measures of control that serious interference with the campaign was avoided.

Although the closely related *Trombicula akamushi* and *T. deliensis* are the only proved vectors of the disease, about 100 new species of Trombiculidae ("chigger mites") have been discovered since 1940—mostly in the Eastern Hemisphere. Despite numerous references in the literature to "blood meals" the larval mites do not ingest blood, but only lymph and tissue fluids. The larvae do not remain attached to the animal hosts for more than three or four days, so that they have never been found attached to the subsequent eschars on patients.

The chief reservoirs of infection of the mite-borne, as of the tick-borne, fevers of the typhus group are believed to be the arthropod vectors, the vertebrate hosts are now regarded as being transitory reservoirs.

The correct nomenclature of the agent is discussed, the name *Rickettsia orientalis* was first applied in 1930, by Nagayo *et al* who had also referred seven years earlier to its apparent rickettsial relationship. The author, however, considers that the name *R. tsutsugamushi* "will be most generally adopted" for the following reasons—(1) Hayashi, in 1920, described a protozoon which he called *Theileria tsutsugamushi*, as the cause of the disease, (2) Various Japanese writers have stated that Hayashi "must have seen rickettsiae in some of his 1920 preparations" so that his specific name by generic transfer deserves acceptance. [Yet the earlier name *Rickettsia nipponica* applied by Sellards is considered inadmissible because its sponsor wrongly reported that he had cultivated the agent.]

The author refers to the pseudo-typhus of Sumatra like most other workers he has overlooked the fact that the disease referred to should be called pseudo-typhoid when translated into English.

The very puzzling differences in the antigens of various strains of the agent are discussed and mention is made of a patient whose complement-fixation titre against a New Guinea antigen was 1-512, whereas against a Burmese antigen the reaction was negative.

A useful map dated 1946 shows the known geographical distribution of mite typhus.

Apart from the influence of combat fatigue and other depressing factors, which caused an increase in the fatality rate, there was evidence of astonishing differences in the virulence of the infection in various localities, for example among 1 469 cases at Owl Birk the fatality rate was only 0.6 per cent, but in smaller outbreaks in Goodenough Island and Finchhaven the rates were 27.5 and 35.3 respectively despite hospital care and the absence of adverse conditions.

A bibliography described as partial contains 30 references. In this short paper of 23 pages the author has succeeded in presenting a clear description of the special features connected with the epidemiology and control of the disease as observed during the second world war.

JOHN B. D. MCGAW

SHEPARD C. C. & HUBBARD R. J. Q Fever in Los Angeles County. Description of some of its Epidemiological Features. *Amer J Pub. Health*. 1948 June v 38 No. 6 781-8.

By this careful epidemiological study the authors have confirmed and extended the findings of previous workers in the U.S.A., but although the disease in man seems to be definitely associated with contact with cattle the mode of transmission, especially to the infected cattle remains a matter for speculation. Proof is still lacking that human infection is acquired from cattle the authors think it possible that cows and human beings may be infected from a common source.

No evidence of transmission by ticks has been found in any of the American outbreaks.

The authors investigated 17 cases which occurred within 10 to 30 miles of the City of Los Angeles in an area in which there were large numbers of dairies where the cows were kept continuously in pens because of the lack of pasture. Eleven of the cases occurred within a period of seven weeks during April and May 1947. The usual hospital diagnosis was atypical or virus pneumonia pneumonia was detected in all the cases investigated by Wray. The complement fixation titre reached a height of 1-64 or over in every case and *Rickettsia burnetii* was isolated from four patients by guinea pig inoculation.

All but two of the patients had either visited dairies or had lived near them, though none had been employed in a dairy or had immediate contact with cows.

Sera of 20 dairy workers in the area were tested - ten reacted at titres of 1-4 to 1-32, though none gave a history pointing clearly to the previous occurrence of an attack of Q fever.

Sera of 163 other persons living in the area, but not connected with the dairies were tested - five reacted at titres of 1-4 to 1-16.

Sera of 93 persons living in the District of Columbia were all negative. Sera of 130 cows from nine dairies in the area were examined - 21 were positive ten of them at titres of 1-64 or over.

The findings suggest that Q fever usually in a mild form, frequently occurs among the cattle dairy workers, and residents near the dairies of the area.

In an Addendum it is stated that since this paper was submitted for publication HUBBARD *et al* have reported the finding of *R. burnetii* in raw milk from four dairies in South California (see this Bulletin 1948 v 45 469). The authors of the present paper were also two of the four authors of the above-mentioned report].

John W. D. McGee

YELLOW FEVER

CALVIN O. R. LAEMBERT H. W. Jr & HAYES G. C. The Home Range of Brazilian Cebus Monkeys in a Region of Small Residual Forests. *Amer J Hyg* 1948 May v 47 No. 3 314-14 3 figs.

Jungle yellow fever in Brazil appears either in an enzootic form in the tropical rain forests or an epizootic form in patchy wooded areas of the central and southern regions. Because no evidence had been obtained that the birds or some species of bats are responsible for the spread of the virus over patchy wooded country during epizootics the present investigation of the role of sylva primates was undertaken.

The region chosen for study was in Minas Gerais, which lay in the path of epidemic which, during the periods from 1934-1940 spread south from the watershed. A similar pandemic spread in 1944 which began to

retrace the path followed 10 years previously. A field laboratory was, therefore, established in front of the epidemic with the intention of initiating investigations before the virus actually arrived.

The country around Passos is characterized by large open pastures. The forested areas are for the most part limited to the steeper hilltops and deeper ravines, where may be found the remnants of climax and young-type forest. These wooded areas are frequently isolated from one another by one or two kilometres of pasture or they may be connected by marginal growth along streams.

During the study, which lasted 15 months, 1,025 monkeys were captured. 62 per cent were taken more than once. Only one animal was found more than 1,000 metres from his home forest and less than 3 per cent of recaptured specimens were known to have travelled distances of 100 to 800 metres across open country.

In a large forest, where there was a number of bands of *Cebus* monkeys, it was rare to find one band wandering into the territory of another. Thus, the normal movements of *Cebus* monkeys do not appear to explain the rapid and extensive spread of yellow fever through the sparsely wooded areas of central and south Brazil.

F O MacCallum

DENGUE AND ALLIED FEVERS

MCCARTHY, D D & WILSON, D Bagster. Dengue in the East African Command. Incidence in relation to *Aedes* Prevalence and some Clinical Features. *Trans Roy Soc Trop Med & Hyg* 1948, July, v 42, No 1, 83-8

This paper deserves attention because of the emphasis laid by the authors on the extreme variability of the manifestations of dengue, a feature which they rightly regard as being responsible for frequent failures to recognize the disease. Only occasional cases had been previously diagnosed in the civilian hospitals of British East Africa, and in the Command itself the diagnosis was rarely made except when an epidemic occurred.

The disease was specially prevalent in Dire Dawa and Harrar in Ethiopia, Mogadishu in Somalia, Diego Suarez in Madagascar, and Mayotte in the Comoro Islands. Cases also occurred in other places in Somalia, in British Somaliland, at Mombasa, and in Mauritius.

At Diego Suarez, the incidence among European units in 1943 was more than 100 per cent, but the rate for all races was only 12.3 per cent. The difference in incidence is attributed to difficulty in recognizing the rash and other features of the disease among Africans. [No mention is made of the probable influence of immunity resulting from previous attacks.]

At Diego Suarez in 1942 many cases were diagnosed as sandfly fever, although *Phlebotomus* was completely absent from the area here and at Mogadishu the French and other residents regarded the yearly outbreaks as due to influenza. Severe pains did not occur. A rash, sometimes lasting only one or two hours, was seen in nearly half of the European patients, but a fully developed rash, rubeoloid or an erythematous background, was seen in only 20 per cent. Dusky redness of the fauces and palate was frequently seen. An alteration of the sense of taste was common, and in some mild cases was the only symptom of which the patients complained.

In 25 per cent of the cases one lymphatic gland or one group of glands was enlarged. Generalized lymphadenitis was never seen. Typical saddle-back

temperature charts formed only 10 per cent. of the total continued, remittent and intermittent types of fever were equally common. A fall of temperature by crisis was the most constant feature of the illness. The pulse was about 100 per minute at the onset soon the rate fell to about 70.

Leucopenia was usually pronounced by the 4th day.

The disease is described as being amazingly variable in its clinical manifestations, with no predominant symptom recurring as characteristic, each symptom taking its turn as the dominant feature.

At Mogulishu the reduction of the *I* Les index from 77 per cent. to 10 per cent. caused almost complete control of the disease. At Diego Suarez, control was not effective till the index fell below 2 per cent.

John W. D. M. Esq.

PLAGUE

SANDOR G. GIRARD G. & SKROMSZ, C. with the collaboration of A. CHEVALLIER. Etude du serum antipesteux de cheval. [Study of Plague Antiserum in the Horse.] *Ann. Inst. Pasteur* 1948, June v 74 No. 6 516-17.

The authors have previously shown that the plague bacillus does not possess a true exotoxin [this *Bulletin* 1947 v 44 900]. The present note brings the matter farther in discussing a study of the antiserum produced by the injection of plague bacilli or toxin. While *P. pestis* contains purely protein antigens which are chemically related to exotoxins, it is shown on immunological grounds from the behaviour of the euglobulin fractions produced that plague antiserum is of the antibacterial and not of the antitoxic type. As the senior author and also Fournier (*Brit. J. Exper. Path.* 1938 19 45) have shown antiserum resistant proteolysis in a weakly acid medium, followed by selective coagulation. In plague antiserum this resistant fraction is absent. The antigen of *P. pestis* are not exotoxins or true toxins but simply bacterial antigens.

H. J. O'D. Burke Esq.

CHARRAUD, A. G. Les arthropodes vecteurs de la peste bubonique. [Arthropod Vectors of Plague.] *Bull. Mus. Hist. Nat. Comp. Paris* 1947 v 22, Nos. 3 & 4 53, 169-200 357-9. Numerous figs.

The Indian Plague Commission of 1907 to 1911 confirmed the findings of the Royal Plague Commission of 1898 previous workers, and subsequent workers that plague was transmitted to man by fleas of the domestic rat. The problem has widened considerably since these fundamental investigations were carried out and especially with the introduction into it of viral plague and its diagnosis. The author has compiled reference work of great utility. He puts forward as a possibility in the epidemiology of plague three distinct cycles: (1) in wild rodents, (2) in domestic rodents, and (3) in man alone.

The first article deals only with wild rodent vector of viral plague. A wealth of information on host species, geographical distribution, and together with references to authority is given in a table listing altogether 111 rodent species. Besides rodents a number of wild animals are attacked by plague among them the primates of *Homopithecus* and *Macaca* and *Alouatta*. The ectoparasitic parasites of the rodents are all listed in the table. A considerable table with details of efficiency of transmission precedes the table and represents much labour.

In the second article dealing with the domestic rodent cycle and the human cycle, the same careful treatment is followed. A second table is given under the heading "spontaneous or experimental infection and experimental transmission of plague by fleas", with columns for species (71), chief host, spontaneous or experimental infection, experimental transmission and authority.

In his summary, the author concludes that "an arthropod can be efficient in the transmission of plague from one *Citellus* to another but incapable of transmission to an animal of another group". "It is now recognized that all the siphonaptera can become plague infected, but are often described as not pestiferous". In no case, however, has the author found a flea incapable of transmission where the following were fulfilled (1) a good crop of fleas (2) The use of the host preferred by the insect. Anatomical considerations may also play a part in transmissibility of plague.

This work is very systematic, and comes from, and with the authority of, Brumpt's Institute in Paris. W F Harvey

TOUMANOFF, C & HÉRIVAUX, A. La nature du sol et le stationnement des puces (*X cheopis* et *X astia*). Essai d'interprétation [The Nature of the Soil and the Habitat of Fleas] *Bull Soc Path Exot* 1948, v 41, Nos 3/4, 293-300 [12 refs]

It is well known that fleas may survive in rat burrows under conditions which, as judged by the general climatic conditions, should have proved lethal. That is easily explained by the fact that climatic conditions inside sheltered places, burrows, cracks and crevices are not the same as those outside. This has led the authors to plead that in the ecology of insects there is a distinction between ecoclimate, a summation complex of meteorological factors, and the "microclimate" which may determine the prevalence or preponderance of a flea-species. The same distinction is to be found in the use of terms like site and "micro-site". In this study two closely allied species of fleas are contrasted, *X cheopis* and *X astia*. The soils or dust and refuse, which experience had shown could be called *cheopis* soils and *astia* soils were analysed and showed a well marked difference. *Cheopis* soil was sandy clay, impermeable to or retentive of water, while *astia* soil was purely sandy. Chemical analysis naturally showed the former to have a high content of colloidal alumina and the latter to have more colloidal silica. Little difference between the pH of the two soils was demonstrable—5.05-5.39.

An old observation of Hirst had emphasized the difference in temperature requirements for the habitat of the two flea species, lower for *X cheopis* than for *X astia*. The question arose therefore whether the chemical characters of *cheopis* and *astia* soils were simply physical and not nutritional requirements, not even a matter of humidity *per se*, but the physical fact that evaporation of water leads to lowering of temperature. This seems to be the opinion, not absolute of course, of the authors themselves. W F Harvey

HOPKINS, G H E. Rats, Fleas and Plagues in Uganda. 54 mimeographed pp., 22 tables & 2 folding maps [23 refs]. Published by permission of the Director of Medical Services, Uganda [Undated]

The text of this report, called a reconnaissance report by the author, may be read with pleasure in its entirety. It is permeated throughout by *scepticism scientifica*, by argument on spurious correlations and by the production again and again of the "negative instance". Nevertheless sharp, crisp well-argued conclusions are drawn from experience, reading and the data available. Uganda is bounded on the north by the Sudan, on the west by Belgian Congo, on the south by

Tanganyika and on the east by Kenya. Kenya blames Uganda for all catastrophic happenings except drought and earthquakes. Uganda is an upland country with a snow-covered mountain Ruwenzori (16 794 ft) descending to Lake Albert (1030 ft) contains the lakes Victoria, Edward and Albert and the Albert and Victoria Nile rivers. Two excellent maps accompany the report.

The author's work on plague, plague rodents and plague fleas may truthfully be set down as pioneer investigation, for the previous surveys of Uganda had reference to typhoid disease and sleeping sickness. Many of the early data are erroneous and cerebral meningitis has been mixed up with plague in African diagnosis. His deductions lead him to the view that plague has existed in Uganda from ancient times, perhaps since 547 B.C., smouldering, latent but never absent. This view of the antiquity of plague in a country though not autochthonous reminds one of the existence of plague in India before the arrival of pandemic plague from Hong Kong to reinforce a negligible smouldering rat enzootic. The subject is well treated by Hankin and was specially investigated in the Kumaon Hills by Walton and Stewart Douglas of the Royal Indian Plague Commission of 1888. But to return to Uganda. There is no sylvatic plague in Uganda and the author throws out a warning that a field rodent dead of apparent plague must be certified as a death due to *P. pestis* and not some other *Pasteurella*, also that it is a vector not a victim of plague. Two invasions are mentioned of Uganda, one of the mammalian vector *Rattus albus* replacing (1901-1906) an equally good plague vector *Rattus (marshomy) conchus n. andulsi* and of *Xenopsylla cheopis*. The flea invasion however seems to have been earlier and to some extent independent of its chief host *Rattus albus*. Nevertheless it is not *X. cheopis* that is the prime plague flea of Uganda, but *X. brasiliensis* which is given as the normal initiator of all plague-outbreaks in Uganda and in many areas in Kenya. *Xenopsylla laurorum* a close relation, was presumably the predecessor of *X. cheopis*.

To conclude when plague occurs in Uganda at the present day four factors are invariably present these being (1) presence of *Rattus albus* (or in the past *R. conchus*) (2) presence of a sufficiently large population of *Xenopsylla brasiliensis* or *X. cheopis* (3) presence of *Pasteurella pestis* and (4) an average rainfall not below about 45 inches. For an epidemic to occur a fifth factor, intimate contact between rats and man is required. A distinction is to be drawn between "huts" and permanent buildings and between corrugated iron roofs and thatch as regards rat infestation. The invading rat *Rattus albus* which is not a burrower and prefers to nest in thatch still finds ample opportunity to nest in the hut with a kerosene-tin or iron roof or in burrows already prepared by *R. conchus*.

HUANG, C. H. HUANG C. Y. CHU L. W. & HUANG T. F. Pneumonic Plague: A Report of Recovery in a Proved Case and a Note on *Salvadorina Propylaxis*. Amer. J. Trop. Med. 1948 May, 28, No. 3, 361-71, 3 figs. (30 refs)

Reports of recovery from pneumonic plague are becoming frequent and, if not recovery, unusual prolongation of life. Few of the cases are uncomplicated as regards therapy. The salient points in the present case are as follows:

A case of pneumonic plague proved morphologically, culturally and experimentally. Presumably contracted in the laboratory by man (33) at commencement of symptoms Feb. 11 1947, subacute fever on Mar. 3 but resolution delayed up and around June 7, sputum bloody, sometimes red, sometimes of tomato-sauce tint, complication of malaria on Mar. 17 due to blood transfusion, *Salvadorina* was started within 48 hours and amounted to a total of 97 gm. between Feb. 13 and Mar. 3 when it was

stopped, because the white cell count had dropped to 3,200/cmm, streptomycin therapy about 72 hours after onset, of which the first intramuscular injection was 100,000 units with similar rather small doses every 3 hours. The dose was later increased to 2-3 million units a day, between Feb 22 and Mar 4 about one million units of penicillin were also given for secondary infections, during treatment 2 blood transfusions, 2 plasma transfusions and 6 intravenous infusions of 5 per cent glucose were given, oxygen inhalation was given as required and 10.2 gm quinine sulphate for malaria, the plague bacillus isolated on Feb 14 was sensitive to both streptomycin and sulphadiazine, that of Feb 26 was resistant to streptomycin, but sensitive to sulphadiazine, the patient had had 2 injections of Haffkine Institute plague vaccine in 1942 and another in China in Dec 1943.

Contacts, 3 of them close, and 15 in all, none of whom had been prophylactically vaccinated, received 3 to 6 gm sulphadiazine daily for adults and proportional doses to children, for one week by the mouth. None of them developed the disease.

One of the conclusions drawn is that sulphadiazine and streptomycin may be more efficacious when used in synergistic combination.

W F Harvey

MEYER, K F, QUAN, S F & LARSON, A. Prophylactic Immunization and Specific Therapy of Experimental Pneumonic Plague. *Amer Rev Tuberculosis* 1948, Apr, v 57, No 4, 312-21, 1 fig & 5 charts

In this short article the authors present experimental methods, histological confirmation and sharp conclusions, which should attract the attention of workers in other organismal infections than plague, where animals are also susceptible with man. The therapy is both prophylactic and curative.

No evidence exists that there is a variety of *P. pestis* which is pneumotropic, and the bacteria isolated from bubonic and pneumonic plague are identical. The animals used in these experiments were guineapigs and mice, which are in some respects contrasted animals in their reactions to the plague bacillus, or rather to the plague toxin. A survival rate of only 21 to 25 per cent in mice after intranasal infection is contrasted with a rate of 80 per cent in guineapigs, the inequality being attributed in part at least "to differences of susceptibility to plague toxin". A careful histological examination, so rare in well-established bacterial diseases, shows the course of the infection after intranasal instillation of highly virulent plague bacilli in animals anaesthetized with barbiturate ("4 to 8 000 organisms per 0.05 cc per mouse and 0.3 cc for guineapigs") — In 5 to 10 minutes one-tenth of the administered bacilli have reached the deeper respiratory passages. Rapid increase of the bacilli is demonstrable in the lungs, so that by the 48th hour 20 to 500 million "may be cultured from the entire mouse lung. At this stage the blood stream is invaded. Guineapigs as a rule are not visibly ill for the first two days but die suddenly between the third and fifth day."

The conclusions will fully reveal the importance of this work. — (1) Intranasal instillation of highly virulent plague bacilli produces in mice, guineapigs and cotton rats a primary pneumonia which is anatomically indistinguishable from that observed in man. (2) Active immunization with avirulent strains of *P. pestis* or chemically killed plague bacilli in the form of particulate antigens confers on mice a definite and on guineapigs a marked protection against an intranasal challenge infection. (3) Concentrated antip plague rabbit sera possess prophylactic and to a slight degree curative values in pneumonic plague. (4) Sulphonamides are not very effective, though "when combined with antip plague serum, their therapeutic value, definite in bubonic plague, is

equally demonstrable in the pneumonic type. (5) Streptomycin is thus far the most effective therapeutic agent known for the treatment of plague infections, both bubonic and pneumonic. Over 80 per cent. of experimentally infected mice when in the septicaemic state of lobular plague pneumonia, may be cured with 5 mg. of streptomycin. It is recommended that human pneumonic plague be treated early in the course of infection with daily doses of 4 to 6 g. of streptomycin and that treatment should continue for not less than six to ten days."

BARNETT S. A. Rat Control in a Plague Outbreak in Malta. *J. Hyg.* 1948 Mar v 48 No. 1 10-18, 1 map, 2 text figs. & 4 figs. on 2 pls [17 refs.]

A straightforward clear account is given by the author of an anti rat campaign in Malta. The rat is the agent in development of plague and the flea-borne endemic murine typhus in the island. In Malta the rat problem was that of a densely populated subtropical area but not wholly urban for the country is intensively cultivated. Human plague had made its appearance on June 17. Altogether in the course of a year since when there have been no further human infections, there were 80 cases with 22 deaths. During this year 22,907 rats were examined, 659 being *R. rattus*. Only 20 rats were diagnosed as plague infected and of these 15 were *R. norvegicus*. It is *R. norvegicus* that is the common rat in Malta and it evidently played an important part in carrying plague. Reliance was placed for reduction of the rat population on poisoning by zinc phosphide arsenious oxide red squill and alphanaphthylthiourea (ANTU). "The method was prebaiting, followed by poisoning with baits and poisons of known efficacy and change of both bait and poison for follow-up treatments."

CHOLERA

IM DER BEEK, M. Die Epidemiologie der Cholera in Frankreich [The Epidemiology of Cholera in France.] *Zucker J. Hyg. u. Infektionskr.* 1948, Apr 1 v 127 Nos. 8-8, 528-34

A historical study

WAKID A. A. A Short Note on Contacts of Cholera at Embaba Fever Hospital. *J. Roy. Egyptian Med. Ass.* 1948 June 31 No. 6 487-8.

The author examined from one to three or more wards each from 600 contact of cholera during the epidemic of 1947. Feces stools were found in 16 persons without symptoms and it is stated that 12 of these were carriers for only two days. The longest duration of the carrier state found was 7 days. Only 3 of the contacts showed evidence of the disease. A dramatic effect of sulpho-namide prophylaxis on the carrier state was observed, nor did this effect appear to be related to cholera vaccination or its absence. Two wards showed latent period of 5 and 6 days with no attack days between the day of isolation and the beginning of the carrier state. (This paper is so much brief further details of these findings would be desirable.)

H. J. O. D. Burckell-Jaffry

HARRIS A. Differential Diagnosis of Cholera. *J. Roy. Egyptian Med. Ass.* 1948 June v 31 No. 6 41-8.

Two went over the first and the last will show the new life of each of the three clinical forms of the cholera of the text books, which is believed true.

vibrio These are "Differentiation of cholera from the clinical point of view is a rather difficult problem" and "Every case of diarrhoea without vomiting should be provisionally suspected as cholera and isolated in the hospital, where the final diagnosis of cholera is either proved or disproved"

Notes on examples of diseases which are mistaken for cholera and which were met with in the hospital at Abbassia form the subject matter of the article. These were (1) food poisoning (2) acute metallic poisoning, (a) the most important, arsenical poisoning, (b) acute mercurial poisoning by mercury chloride taken suicidally (3) severe types of dysenteries, (a) bacillary dysentery, (b) amoebic dysentery, (c) malarial dysentery, (d) bilharzial dysentery, (e) ciliate dysentery. [There is no mention of vibrio dysentery, El Tor dysentery, so that presumably it was not met with, or was included with true cholera.] (4) pellagra (5) tuberculous enteritis (6) some mild forms of diarrhoea post-prandial, nervous, gastrogenous or an intestinal carbohydrate dyspepsia (7) acute appendicitis (8) Addisonian crises (9) Graves's disease (10) summer diarrhoea, "cholera infantum" (11) some others. The author draws attention to uraemia, a terminal feature of cholera, to remark that "uraemia itself due to kidney disease or other factors gives rise to diarrhoea, vomiting, dehydration, and acidosis—a picture very similar to cholera"

W F Harvey

BALIGH, A. **Complications encountered among Cholera Cases treated in Ismailia Isolation Camp** *J Roy Egyptian Med Ass* 1948, June, v 31, No 6, 468-70

The commonest complication of cholera encountered by the author was *heart failure*. This occurred in (1) most of those patients dying within 24 hours of admission as a result of sudden changes in the blood and ischaemia, (2) sometimes during treatment with large transfusions given rapidly, (2) occasionally during apparent convalescence as a result of toxæmia and myocarditis. Extra-systoles were quite common at this stage, but corrected equilibrium of the blood soon caused them to disappear. Electrocardiographic examinations confirmed that the heart may be so deranged in severe cholera as to fail at any moment during convalescence. In fact 8 apparently well patients did die suddenly at this stage in 10 to 20 days from the onset of the disease.

Persistent suppression of urine and uraemia caused many of the early deaths before lines of treatment were completely established. It was usually due to dehydration and retention of nitrogenous products.

Abortion and premature labour were constant in those pregnant women who had cholera. Of 7 such, 4 aborted, 2 had premature labour and 1 died during labour at term. All of them died within 2 to 3 days, except 1 who died of pneumonia in 5 days. These abortions were complete and without haemorrhage and were attributed to severe purgation, severe reflex uterine contractions and toxæmia. The author does not recommend any interference in such cases, as the abortions were always completed quickly without it.

Five patients died of *pneumonia* and 2 from *pulmonary oedema*, both of the latter suffered from suppression of urine, but the author adds that "oedema was due to sudden overhydration with saline solution". During the recovery stage, 3 patients developed *maniacal conditions*, 1 recovered completely and the other two died.

Parotitis and paraplegia each occurred once and cure was complete in each case.

[The statistical value of this note would have been enhanced by a statement of the total number of cases seen]

H J O'D Burke-Gaffney

LAMIR, S. C. Sulphadiazine and Sulphaguanidine in Cholera. *Indian Med Gaz.* 1948 Jan., v 83, No. 1 74-8.

Most of the work on the value of sulphonamides in cholera has gone to show the superior value of sulphaguanidine over the other forms as being non-absorbable and non-toxic. In this study the author uses sulphadiazine less toxic than sulphathiazole in the initial dose of 2 gm. followed by 1 gm. 4 times a day as a comparison with sulphaguanidine. Of course in cholera symptomatic treatment is always required to combat dehydration demineralization and depletion of colloids. Altogether 139 patients received sulphadiazine 111 sulphaguanidine and 43 got calomel. The result is interesting. Both sulphaguanidine and sulphadiazine are beneficial in cholera. If children and old men are excluded the death rate for the intermediate age group, the majority group, is practically the same with both drugs—8.68 per cent. with sulphadiazine and 8.49 per cent. with sulphaguanidine. W. F. Hurry

GOHAR, M. A. & ISA, A. A. Cholera Vaccines. *J Trop Med. & Hyg.* 1949 July v 51 No. 7 144-7

Gohar has seized the opportunity of the cholera epidemic in Egypt to make useful animal experimentation on vaccines, using the Horein strain itself for this purpose. The animals used were rats and the LD₅₀ intraperitoneal dose of the Horein cholera vibrio was 4 000 million organisms. His five vaccines, for each of which 25 rats were provided were (1) Heat killed phenol-preserved suspension, at 4 000 million/ml. of which the lethal dose subcutaneously was 4 ml. (2) Formalin-killed phenol preserved suspension, of the same strength and having the same lethality as the first. (3) Soluble extract obtained by adding an equal quantity of normal sodium hydroxide to a suspension at 8 000 million/ml. incubating at 37°C for a few hours until clear and neutralizing with HCl to pH 7.5. The lethal subcutaneous dose was 3.5 ml. (4) Toxoid obtained by treating the No. 3 toxin with 0.7 per cent. formalin and incubating at 37°C for 70 days, by which time it had become non-toxic and the animals immunized with it could resist big doses of toxin. (5) A mixture in equal parts of vaccine and toxoid.

Also, three batches of rats were used the 6th being the control untreated batch the test dose the LD₅₀ and the immunizing dosage 2,000 and 4,000 million organisms or equivalent subcutaneously at weekly intervals. The survivals of the 6 batches in the order given were 16 17 15 14 21 and 11 or in percentages, 64 68 60 56 84 44. It must be admitted that the number of animals used is too small and the results obtained can only be looked upon as suggestive in favour of the mixture containing equal parts of both the usual and accurate.

An important remark made by the author while commenting doubtfully on the distinction between haemolysation and haemolysis by slants may be recorded. We found when cultures of the Horein vibrio were kept in the incubator for three days that the clearing was just as intense as that produced by the truly haemolytic El Tor vibrio, thus showing that the difference between the two organisms is more of quantitative than a qualitative nature.

The toxoid vaccine mixture takes long time by complicated procedure to prepare and the author describe a simple method of preparing an alum precipitated cholera vaccine mixture see this Bulletin 1949 45 501.

AMOEBIASIS AND INTESTINAL PROTOZOAL INFECTIONS

- SHAFER, J G, RYDEN, F W & FRYE, W W Studies on the Growth Requirements of *Endamoeba histolytica* III The Growth and Multiplication of Two Strains of *E histolytica* in a Transparent Medium without the Addition of Rice Flour or other Particulate Matter and without Demonstrable Bacterial Growth *Amer J Hyg* 1948, May, v 47, No 3, 345-50

The culture of *Entamoeba histolytica* in the absence of bacteria has been attempted for a long time, and these workers have progressed a further step towards the goal. They used a medium consisting of (a) the supernatant fluid from a culture of a streptobacillus [this *Bulletin*, 1948, v 45, 786, 787] in a thoglycollate rice flour medium, (b) a bacteria-free filtrate of the specific bacteria complex grown in egg-slope-buffered-saline medium, (c) normal horse serum, and (d) a low concentration of penicillin. Amoebae obtained from fresh specimens could not be grown directly in this medium, they first had to be passed through media containing higher amounts of antibiotics. The culture must be anaerobic and subcultures should be performed every 48 hours (at 37.5°C). The few streptobacilli present in the cultures either fail to multiply or die out—even after 14 days the medium remains clean. P C C Garnham

- STEWART, G T & JONES, W R The Pathology of an Experimental Amoebic Infection in the Rat *Ann Trop Med & Parasit* 1948, Apr, v 42, No 1, 33-45, 5 text figs & 2 pls [36 refs]

By the technique described by JONES [this *Bulletin*, 1947, v 44, 313] rats were inoculated intracaeally with *E histolytica*. In different groups, 67-90 per cent of the animals became infected. The inoculum was 0.2 cc of the mixed centrifuged deposit of amoebic culture with an equal volume of the mixed gastric mucin. For the study of bacterial action, broth cultures of bacteria were added to the inoculum or were given orally before or after establishment of the amoebic infection. Heavy doses of bacteria ranging from 10 to 1,000 million organisms were administered. In certain experiments, phthalyl sulphathiazole (500 mgm/kgm orally) or penicillin (500 units subcutaneously) was given four times in the 48-54 hours before or after the operation. After periods ranging from 1 to 14 days the animals were killed and the caeca examined. The infection was judged by the numbers 5 to 0, according to the degree of infection. Heavy infection, ulceration, numerous amoebae, 5, inflammation and mucus numerous amoebae, 4, inflammation, many amoebae, 3, normal, many amoebae, 2, normal, few amoebae, 1, normal, no amoebae, 0. For two strains of *E histolytica* the infectivity and virulence were definitely related, but one strain gave a high percentage of virulent infections unrelated to the infectivity. The mucosa of the caecum showed evidence of invasion within 24 hours in the shape of minute erosions of the columnar epithelium. Later there was invasion of the villi and crypts by amoebae with some necrosis of the adjacent mucosa. At a later stage the mucosa at the edge of the lesion became heaped up and formed a follicular ulcer containing mucus and amoebae. Beyond the ulcer the mucosa remained healthy. In another type of lesion there was widespread cellular infiltration by polymorphonuclear leucocytes of the tissues around the original break in the mucosa. There was congestion and focal lymphoid hyperplasia. Amoebae were often scanty. Lesions of this type were especially prevalent when virulent bacteria had been administered in the inoculum. Between these two types of lesion many intermediate forms occurred. At a later stage (3-7 days) the caecum was grossly ulcerated and thickened with

a copious exudation of mucus into the lumen and local peritonitis leading to adhesions. Amoebae were found chiefly in the bases of the ulcers or in the loose exudate sometimes forming a solid mass. Isolated amoebae were seen in the submucosa and rarely outside the muscularis mucosae. If ulcers would begin at any time but usually commenced after seven days. In some cases this was retarded for a few weeks. Death sometimes occurred after 3-4 days but most fatalities were during the first 24 hours and were associated with coliform bacteraemia. No amoebae were observed in the liver.

The lesions were aggravated by the administration of *Bactera* and paracolon bacteria. The strain of paracolon remained in the bowel for several days. The administration of penicillin controlled the bacteria and profoundly reduced the severity of the infection. Penicillin was active both prophylactically and therapeutically. Phthalyl sulphathiazole and other sulphonamides were partially effective prophylactically but had no therapeutic effect though given with penicillin they seemed to increase its activity. The result of the work is that young laboratory rats are susceptible to amoebic infection, the bacterial flora being the major factor in the pathogenesis. With the bacteria controlled by penicillin minimal lesions are produced. In some of the young rats after the acute infection had subsided, cysts were found in the intestine. In general, the infection resembles that in human beings.

GHOSH, N. N. GHOSH, H. & RAY, J. C. A Preliminary Note on Complement-Fixation Reaction in Amoebiasis. *Indian Bioclinical & Exper. Med. Calcutta*, 1948, Jan. Feb. v 8, Nos. 1/2, 3-10. [21 refs.]

The serological diagnosis of amoebiasis has been re-examined with a view to the preparation of a more satisfactory antigen for the complement deviation test than has previously been devised. An antigen was prepared from cultures of a strain of *E. histolytica* virulent to kittens by penning down the amoebae in the supernatant fluid of cultures at 1000 r.p.m. for three minutes. At this speed the major portion of the accompanying bacteria was left in the supernatant fluid, which was discarded. The washed sediment was triturated in sand to a fine paste and diluted in phenolized distilled water (0.4 per cent. phenol) to nine times its volume. After filtration through filter paper it was stored in the ice chest until required for use. The working dilution of this antigen was 1 in 10 and it was employed with a deep-cell haemolytic system. The serum under test was inactivated at 55°C. for half an hour and diluted to 1 in 5 before use. Control bacterial antigen were also prepared from the amoeba culture-tube.

The authors found their antigen more potent and specific than those prepared by alcohol extraction methods. Of 14 persons giving a positive complement deviation test 7 proved to have minimal *E. histolytica* infections and 7 had amoebic liver abscesses. Of 46 persons giving a negative test 2 were found to harbour *E. histolytica* both of these were free from symptoms of the infection. The table setting out these results is somewhat difficult to follow.

A. H. D. Allen

STEWART, G. T. O'MEARA, P. J. & KIRKMAN, W. L. Observations on Amoebiasis in Ceylon. *J. Ind. Med.* 1948 Jan. 34 No. 1. 1-7. [24 refs.]

The authors are in agreement with the beginning of the work with fall in the number of amoebae in the culture and was a fairly reliable indicator of the state of the infection. The number of amoebae in the culture at two or three days after the start of the work

Faeces of Asiatic cooks and stewards in three establishments in the different climatic zones of Ceylon were examined by the copper sulphate flotation method. In the low country it was 9 per cent, at Diyatalawa, up country, 13 per cent, and in Trincomalee, low country dry zone, 11 per cent. It is to be noted that the percentage of incidence when four specimens were examined was approximately twice as great as when only one was examined. The influence of such a carrier state on the incidence of fresh infections in Europeans exposed to contagion is given in a table which purports to show that the incidence of fresh cases progressively diminished as the food-handlers were effectively supervised. In the majority of instances it seemed likely that constant exposure to infection first occurred in the mess. After a survey in December, 1944, three cooks and eight stewards were found infected with *E. histolytica* and were either treated or transferred to other duties. Thereafter infected food handlers were excluded and this was associated with an abrupt decline of fresh cases. Other means of acquiring infection were eliminated as far as possible. No uncooked fresh vegetables were served and flies were not abundant. A similar fall of incidence occurred in Trincomalee in June 1946 after similar measures had been taken.

Admissions for bacillary dysentery at some periods exceeded those for amoebiasis, and in some a sharp attack of bacillary infection appeared to unmask a latent amoebic infection. But bacillary dysentery rarely caused permanent injury. In this respect amoebiasis was in contrast. Severe cases, complications and relapses were comparatively common and about a quarter relapsed within a few months. The danger of reinfection was high. There were no fatalities among Europeans, but general impairment of health was a serious problem.

The slow onset is shown by a table which indicates that 68 per cent had been in the station more than six months before the onset of symptoms. The remaining 32 per cent seem to indicate that signs of infection may develop in less than six months, but for the most part the patients were in good general condition.

In each case diagnosis was made by faeces examination and in a few by rectal scrapings.

The main clinical features are tabulated. Diarrhoea occurred in 84 per cent, constipation in 10, abdominal discomfort in 81 and tenderness in 59, blood in stools in 49, vomiting in 18 and nausea in 16, loss of weight in 11, pyrexia in 14 and lassitude in 16.

As regards diarrhoea there was a loose precipitate morning stool, but as such an occurrence is frequent in normal individuals, the best pointer for diagnosis seems to lie in recurrent diarrhoea or alteration of the bowel habit.

Sixty-seven cases were dysenteric, but the remainder (73) were diagnosed as amoebiasis from the presence of *E. histolytica* cysts in the faeces.

Severe cachexia and signs of nutritional deficiency were rare and occurred only in patients with relatively long histories of illness.

Plasma protein estimations were performed upon a random sample of 26 patients of which six showed significant degrees of hypoproteinaemia, each being a severe relapsing case. Lowering of plasma proteins in certain cases has been adduced as evidence of nutritional deficiency in amoebiasis, but it is possible that hypoproteinaemia may be a manifestation of liver damage. Pyrexia was mild and lasted only 24 hours. When persistent and high it was associated with definite signs of hepatitis and once with massive typhlitis.

Sigmoidoscopy—The classical lesions are not in dispute, but some of the early changes are still ill defined. Pin-point craters, patchy hyperaemia and localized oedema were observed in cyst passers—changes which were best seen with a snuffing eye-piece.

Raised pin-point yellowish dots with an inflammatory areola were often seen at the recto-sigmoid junction. These scrapings usually yielded vegetative amoebae but occasionally mucoid material with a few macrophages and leucocytes. A day or two later stool examination or sigmoidoscopic scraping, revealed *E. histolytica*.

Six cases of amoebic hepatitis were seen during the period of review. Haemorrhoids and pruritus ani were not uncommon but the most troublesome complication was post-dysenteric colitis. Apart from *Shigella* infections (biliary dysentery) the nature of secondary infection still awaits definition. In their experience this occurs only in late and relapsing cases but clinical evidence is obtained only when the exudate becomes purulent. As regards treatment no original methods are claimed. Emetine injections were given during the dysenteric phase or where hepatitis was suspected sulphonamides, occasionally with penicillin, where the appearance of frank pus in the stools suggested the presence of heavy secondary infection. EBI quinoxyl and stovarsol were given for the remainder of the course.

Criteria of cure were Twelve negative stools for *E. histolytica* and exudate sigmoidoscopy, no active lesions, not more than three bowel movements per day.

The relapse rate between dysenteric and non-dysenteric cases was remarkably similar which suggests that a patient with dysentery has as good a chance of cure as one passing cysts.

The custom of giving ten or twelve injections of emetine to every case has been to a great extent abandoned, but the authors, on the supposition that vegetative amoebae in lesions of the upper colon become transformed into cysts in the lower colon, suggest that there may be good reason for its continuance in patients without dysenteric symptoms. [See also this *Bullet* 1948, v 43, 357 1947 v 44 818.] P. M. von-Bahr

HULLASHO, A. L. Amoebiasis hepatica. [Liver Amoebiasis.] *Netherl. Tijdschr. Geneesk.* 1948, July 4 v 92 (iii) No. 30, 2214-20.

PARKER, L. G. On the Relative Efficacy of Emetine in Intestinal and Hepatic Amoebiasis. *P. & Soc. E. Afr. Biol. & Med.* 1948, June v 68, No. 2, 362-3.

It is well known that while emetine is effective in amoebic hepatitis and early amoebic abscesses, it is ineffective by itself in amoebic dysentery. This is usually explained on the grounds that the drug is capable of destroying trophozoites but not cysts of *E. histolytica* and one cyst or not usually found in the tissues outside the intestinal lumen. hepatic amoebiasis is more susceptible to emetine treatment. This does not however explain why the drug can eradicate trophozoites in the liver and although emetine has been used in amoebiasis for more than 33 years the full answer is that the tissue distribution and concentration of this alkali has not been reported.

Working in the Pharmacology Section, Research and Clinical School, Army Medical Centre, Washington D.C. the author injected 1 albino rabbit (3 kgm. weight) intramuscularly with 8 mgm. kgm. emetine hydrochloride in aqueous solution. The rabbit was sacrificed in groups of 3 at intervals of 1 hour to 28 days. The excreta and tissues were analysed for emetine by a method adapted from that of B. A. C. PARKER and DIST. [this *Bullet* 1947 v 44 90]

The results for 28 days are shown in table which indicates that within an hour the concentration of emetine in the liver was 4.9 mgm. kgm. compared with 5.5 in the intestine. At 1 hour the figures were 41.8 and 1.7 respectively.

and in 4 days 15.4 and 1.2 mgm./kgm. Thereafter the drug continued to be found in the liver in decreasing quantities up to the 28th day, while none was detected in the intestine from the 5th day onwards.

The finding of a high concentration and prolonged presence of emetine in the liver, compared with low concentration and transient presence in the intestine, is put forward as the explanation for the efficacy of the drug in hepatic amoebiasis and its failure in amoebic dysentery in man. [While one hesitates to argue from animal to man in experiments of this nature, the highly significant results of these experiments and their possible implications demand further and extended investigations on this important point.]

H. J. O'D. Burke-Gaffney

DWORK, K. G. The Use of Para-Aminobenzoic Acid in Amebiasis. Preliminary Report. *Bull. New York Acad. Med.* 1948, June, v. 24, No. 6, 391-3.

This study was conducted in the Department of Health, New York City, on 12 out-patients with *E. histolytica* infections, all but one of whom were Porto Rican emigrants. As the drug, which is rapidly excreted, was not given at night and no blood levels were done, it was believed that if encouraging results followed, even more favourable results might be expected under hospital conditions. The drug used was the sodium salt of paraaminobenzoic acid (sodium paba).

The dosage of sodium paba employed is not stated in the text, but in a table listing individual results, sodium paba treatment is shown as varying from "2.0 q3h 7 days" to "2.0 q2h 14 days" which presumably means 2 gm. every 3 hours for 7 days to 2 gm. every 2 hours for 14 days.

Nine patients completed the course and four of them had negative stools after 4 to 30 weeks. Of seven patients with symptoms, six showed improvement or disappearance of symptoms after treatment.

It is noted that the non-Porto Rican case had been refractory to carbarsone therapy but cleared up with sodium paba.

Another table shows that the successes were obtained in four of the five patients who received the drug at intervals of 2 hours, and that of the five failures four occurred in those treated at intervals of 3 or 4 hours [see also BRACKETT and BLIZNICK, this *Bulletin*, 1948, v. 45, 80].

H. J. O'D. Burke-Gaffney

YOUNG, Viola M. & FELSENFELD, O. The Occurrence of Intestinal Protozoa in Adults in San Juan, Puerto Rico. *J. Parasitology* 1948, June, v. 34, No. 3, 229-30.

The authors refer to previous surveys of intestinal protozoa in Porto Rico by POINDEXTER [this *Bulletin*, 1934, v. 31, 281], FAUST *et al.* (*Puerto Rico J. Pub. Health & Trop. Med.*, 1933, v. 9, 447), and ACOSTA MATEÑO (*ibid.* 1946, v. 21, 369). The difference in scope and methods of these surveys is pointed out and the authors then describe the present survey designed to ascertain the existing endemicity of intestinal protozoal infections in San Juan and suburbs.

They obtained fresh stools from 600 adult patients, without diarrhoea, in the Presbyterian Hospital of San Juan. The patients in this hospital represented all ages and classes of the general population, but no children were included in this survey. The stools were examined by direct smear and by zinc flotation (Faust).

The results are shown in a table and compared with those of the previous three surveys. It is pointed out that ACOSTA MATEÑO considered her percentages too low as she only used direct smear. This is reflected in the present survey where protozoa were found more frequently.

E. histolytica was found in 17.33 per cent. of persons compared with 1-4 per cent. in Pomdexter's survey and 14.3 per cent. in Faust's rural survey 15 years ago. On the other hand, *Giardia intestinalis* (3.83 per cent.) and *Isospora hominis* (1.83) were considerably fewer which may have been due to improved sanitary conditions and to the exclusion of children from the present survey. It was observed that 23.5 per cent. of persons harboured *Endolimax nana* compared with 16.3 in Faust's survey, which the authors believe may be due to frequent shifts of population from the Continental United States where this parasite is said to be increasing.

Protozoa were found in 57.16 per cent. of the persons examined: two species were found in 14 per cent., three in 8.5 per cent., and four in 0.5 per cent.

The authors point out that the incidence of *E. histolytica* in symptomatic adults has not receded during recent years from the high rates found by FAUST *et al.* Frank clinical amoebiasis is rarely found in the San Juan area, but the present findings indicate that the danger of it persists in Puerto Rico. [The date of the paper by FAUST *et al.* is incorrectly given in the list of references as 1943.]

LEIS, CAROL E. *Giardiasis intestinalis y síndrome convulsivo* [Intestinal Giardiasis and the Convulsive Syndrome.] *Revista Médica Argentina*, 1948, June 4, v. 35 No. 23, 1694-7.

An account of a case and discussion.

GLAUBER, W. *Massive Infektion mit Isospora hominis s. Bel.* [Massive Infection with *Isospora hominis*.] *Med. Klin.* 1948 Jan., v. 43 No. 1, 20.

This note concerns a refugee from Sudetenland who was admitted in August 1946 in a comatose condition. His illness had started suddenly a week before with profuse watery diarrhoea. He was very ill and the condition suggested a diagnosis of typhoid. General and laboratory examinations, including agglutination, did not provide a diagnosis but microscopic examination of the stools showed masses of coccidia of the type *Isospora hominis* (see p. 1007). In a single microscopic field with the oil immersion lens, 5 to 6 coccidia were seen. A brief description of the parasites given. The condition resisted sulphonamide therapy but apparently responded to treatment with Rivanollettes. 2 tablets 3 times daily (1 tablet contains 0.025 gm. of Rivanollettes) for a week. After 2 days the stools were formed and after 4 the coccidia were no longer detectable in them. Fourteen days after the course of treatment the patient had put on 10 lb. in weight. He has been followed up for a year: no relapses have occurred and he is fit for work.

The author discusses the differential diagnosis of acute diarrhoea of this nature and refers to the uncertain pathology of coccidiosis. It should be kept in mind when one is dealing with sulphonamide resistant diarrhoeas, the prompt response to Rivanollettes in this case was remarkable. This claim of a severe condition attributed to infection by *Isospora hominis* and its dramatic cure is worthy of more detailed evidence in support of it.

H. J. O'D. Burke-Gaffney

LAMY, L., MARCHAL, G. & CHEVRIER, A. M. *Nouveaux données sur un Eurytomus parasite de l'intestin de l'homme*. Further Notes on an Eurytomus Parasite in the Human Intestine. *Bull. Soc. Path. Exot.* 1948, 41 No. 34, 154-8, figs.

Under the name *Eurytomus hertzi* O'D. the authors describe a flagellate which was grown in culture from the faeces of three unusual subjects who

suffered from diarrhoea. The flagellate was globular and measured on an average $7\ \mu$ in diameter. There was a large nucleus and three long flagella arising from a point near the nucleus. In addition, in the majority of flagellates, a club-shaped process $4\ \mu$ in length arose from the body. The flagellate was not found on microscopic examination of the faeces and the authors conclude that it must have been present in the encysted stage which was responsible for the growth in culture. They discuss the nomenclature of the organism and place it in FONSECA's genus *Enteromonas*, though he gave no account of the club-shaped process. Because of the process they place it in a new species as *E. hervei*, but it seems probable that the presence of the process would justify a different genus from *Enteromonas*.

LEPROSY

McCoy, G W *Leprosy in California—Danger of Infection* Pub Health Rep Wash 1948, May 28, v 63, No 22, 705-12

This is a careful study of the conditions under which leprosy infections occur in the mildly endemic area of California, with an incidence only exceeded in the United States by the defined endemic areas of Louisiana, Florida and Texas. Among 475 cases up to 1940 not more than 14 appear to have been infected in California itself. The main sources of imported infection were, first, China and other Far Eastern countries, and second, the neighbouring endemic areas of Mexico and Louisiana, a very large majority being males. The present inquiry deals for the first time with probable infections within the State, by studying the data accumulated by the health department and the Louisiana state leprosarium. The data were collected by interviewing the patients, three family group infections were found among those who had lived in California all their lives, seven out of eight of whom had lived with leprosy parents, three were examples of conjugal infections. Among approximately 500 cases inquired into, only 23 appear to have been infected in California itself, this places the State on a level with Minnesota as a mildly endemic area. It also appears that 8 of the infections occurred in a small area in the middle of the State, 6 of them were in children infected by their parents, apart from which the likelihood of infection in the area is very small.

BRAGA, R V Contribuição ao estudo da lepra no meio proletário da cidade de Rio de Janeiro [*Leprosy among the Poorer Classes in Rio de Janeiro*] *Rev Argentina Dermatofilologia* 1947, July-Dec, v 31, Nos 3/4, 486-92, 7 graphs

During a period of years (August 1939-47), 66,764 industrial workers were examined in Rio de Janeiro, 3,006 were suffering from dermatosis of some kind and 231 were infected with leprosy, i.e. 0.35 per cent of the total and 7 per cent of those with skin lesions. By a series of graphs other details are indicated. The greatest number in any one year was 39 in 1944 and the smallest 20 in 1941, the average being 29 *per annum*. As regards the clinical forms, 93 were of the nerve type, 40 lepromatous and 98 mixed, 196 of the total were males, 35 were females [but as the respective totals are not given, this has little if any meaning, all that is stated is "the number of male operatives was greater"], 185 were Brazilians, chiefly from Rio, Minas Gerais and São Paulo, 38 Portuguese, and 8 of other nations. Those engaged in work liable to be associated with trauma were the most attacked—stone-masons, metal workers and mechanics.

BECHTOLD L. M. Da conveniência de se fazer a lepromina-reação nos funcionários que trabalham em contacto directo com o doente do lepra. [Importance of subjecting Attendants on Lepers to the Lepromin Reaction.] *Rev. I. ginec. Dermatol. fisiologia*, 1947 July Dec., v 31 Nos. 34 484-5.

The prognostic value of the lepromin reaction is well known to leprologists. If lepromatous are negative and the tuberculoid positive in the majority of cases and ROSENBERG has reported that reactivation of lepromata is common among the lepromin-negative and that positive reactors do not acquire the disease or if they do the evolution is that of the tuberculoid type. Hence the author proposes that the test should be carried out on all who are about to work in direct contact with leprosy patients. Even those who give no history of contact with patients may give a delayed positive. Those working in leprosaria who react positively may continue in their work, but should be watched so that if they become negative, they may change their occupation and be entitled to favourable consideration of a request for compensation. Observations tend to show that it is rare for healthy officials to contract the disease: seven who have shown symptoms had been in contact with lepers before entering on their duties and one only gave no such history. But though the number may be small, there is no doubt that the possible danger exists and it would be foolish to neglect precautionary measures. *H. Harold Scott*

OLAVO CASTRO N. MACIEL, P. B. & BONATTI, A. A. Reacção, sedimentação de flocculação em lepra. Su aplicação prática nel diagnóstico e profilaxia [The Flocculation Reaction in Leprosy] *Rev. I. ginec. Dermatol. fisiologia* 1947 July Dec., v 31 Nos. 34 328-31

CASTRO and BONATTI in 1945 recorded some results with sera of leprosy patients and an antigen with lepromata (see this *Bull.* 1946 43, 849-850, where details of the antigen preparation are given). The authors now report the result of the test in a large number of cases, 1,816, of whom 224 were suffering from leprosy (162 the lepromatous form, 62 the tuberculoid) and 1,592 either healthy subjects (1,108) or suffering from other diseases (syphilis, pulmonary tuberculosis, parasitic infections (malaria, American trypanosomiasis, leishmaniasis), brucellosis, typhoid, etc.) and 101 contact of leprosy. Of the 162 of the lepromatous group 118 (73.5 per cent.) gave a positive flocculation, only 3 of 62 (4.8 per cent.) of the tuberculoid type, so that 122 out of 224 (54.4 per cent.). Of the 1,108 healthy subjects 7 reacted positively, of the 101 contact 4 (3.9) were positive. Only 10 of the 1,592 healthy and other diseases patients gave flocculation. Of these 4 as stated, were living with leprosy patients. 3 gave a very strong, 1 had tuberculosis caecum in the lungs and died soon afterwards, only 1 was clinically healthy. *H. Harold Scott*

SCHULMAN S. Influencia benéfica de la reacción leprosa en la evolución de los casos lepromatosos. Good Effect of the Leprous Reaction in the Evolution of Lepromatous Cases. *Rev. I. ginec. Dermatol. fisiologia* 1947 July Dec. 31 Nos. 34 483-1m, 2-4m. English summary.

Ten years ago Dr de Souza Lima told the author that leprosy patients seemed to be followed by improvement. Lepromatous patients and that in the progress of their disease. The author has now studied this problem in 33 patients 2 females, but the cutaneous and visceral, the ocular lesions

Speaking of the skin lesions, 12 of the 33 improved and all had had leprosy reactions, 7 remained stationary and again all had had the reaction, 14 were worse and of these 4 had had the reaction, 10 had not. Of the 31 with ocular lesions who were studied, 21 had had the reaction and of these in 13 the eye condition had remained stationary and in 8 was worse. Two cases are recorded no such reaction 2 were stationary and 8 were worse. With photographs of the patients in detail illustrating the first of these points, both were L_3 cases showing the changes which took place, therefore, from those of BECHELLI and The author's conclusions differ, therefore, from those of BECHELLI and COSTA VALENTE of São Paulo (*Rev Brasileira de Leprologia*, 1937, v 5, Special Number, p 167) who stated that, though some might improve, the majority became worse after the reactions

SCHUJMAN, S & CASTAÑÉ DECOUD, Anibal Modificaciones histopatológicas comprobadas en casos lepromatosos beneficiados (a) Con tratamiento chaulmoógrico (b) Con tratamiento prominico (a) Con tratamiento in Lepromatous Patients treated with (a) Chaulmoogra, (b) Promin] *Rev Argentina Dermatofisiologia* 1947, July-Dec, v 31, Nos 3/4, 502-6, 4 figs English summary

The authors treated 30 lepromatous patients with chaulmoogra and 10 with promin. From 7 of the former and 2 of the latter biopsy specimens of the skin were taken, one at the start of the treatment, the other later when there was only a residual lesion. Some had biopsies at intermediate stages. The changes are shown by four microphotographic reproductions and the details of the different parts of the skin section in each of the nine are described in a table. These may be summed up by saying that the infiltration of the dermis is much reduced, the corium is thickened owing to reabsorption of the infiltrated area, the bacilli are reduced in numbers and broken up, in some no bacilli can be seen at all. These changes were seen in those treated with either drug, chaulmoogra or promin

FIOL, H, JONQUIERES, E D L, BRUSCO, C M, MELAMED, A J & FIRPO, C J Tratamiento de la lepra con promin (promamida) [The Treatment of Leprosy with Promin] *Rev Argentina Dermatofisiologia* 1947, July-Dec, v 31, Nos 3/4, 531-7

The results of treatment by promin of 125 patients suffering with the lepromatous type of leprosy are reported. Forty-three had had less than 6 months' treatment and of these 30 [stated as 69.7 per cent] were improved, 12 remained the same and one was worse, of 71 who had had 6-12 months' treatment 47 (66.2 per cent) were improved and 24 unchanged, none was worse, of 11 who had had more than one year's treatment 10 were better and one unchanged. Tables are given presenting the results in other ways. First, according to total dosage of the drug. Four had received from 900 to 1,300 gm and all had improved, 36 had had 500-900 gm and of these 28 were better, 7 stationary, and one worse, of 85 with less than 500 gm 55 were better and 30 unchanged, none was worse. Another table gives the daily dosage and results. Of 13 receiving up to 1 gm daily 7 were better, 6 stationary, of 59 receiving 1-1.9 gm 38 were better, 10 stationary, 8 received between 3 and 7 gm daily and 7 improved, one remained unchanged. In 106 the Mitsuda reaction was carried out, 6 were marked, 4 weak, and 96 negative. The results would be still better, say the authors, if chaulmoogra were given at the same time and other adjuvant treatment such as liver, vitamins, general tonics and such like

FRANCO, A. Dr. de Souza Lima told the author that lepromatous reaction seemed to be followed by improvement of lepromatous patients and to retard progress of their disease. The author has now studied this question in patients as regards, first, the cutaneous and second, the ocular lesions.

HELMINTHIASIS

GAUD, J., FAURÉ & SOLÉ Variations dans le temps des index d'infestation humaine dans la bilharziose vésicale marocaine [Temporary Variations in the Indices of *S. haematobium* Infection in Morocco] *Bull Inst Hyg Maroc* 1946, v 6, 55-60 [10 refs]

Schistosomiasis is usually considered to be an endemic disease, not subject to great fluctuations in incidence, but the authors, as a result of investigations made in Morocco during the period 1940-44, have revised their views in this matter. They quote, for 4 foci of *S. haematobium* infection, the findings of previous investigators, and their own more recent figures, and show that in most of the villages the recent figures are much lower than the earlier figures. In the more recent investigations, moreover, *Bulinus* snails were not easily found. [In one of the tables only the percentages of positive findings are recorded, and in some of the villages the number of persons examined is small, so that the incidence, as calculated must be subject to very large chance of error, nevertheless, the total figures are big enough to justify the opinion that there has been a considerable reduction in incidence.]

They discuss the possible reasons for these differences, which may be as much as 10 to 1 and are usually 3 to 1. Differences in technique are not probable, and treatment cannot account for the change, because in some of the areas it was not given. There may be a seasonal factor, and the examinations were not always made at the same time of the year, but it is unlikely to be important. It seems as if *S. haematobium* infection behaves as an epidemic disease, and that when human infection is comparatively rare the adult infection rate is higher than the childhood rate, and the snails are scanty. The disease is relatively benign in Morocco.

Charles Wilcocks

SCHWETZ, J. Sur l'état sanitaire de la région du Lubilash et tout spécialement sur la bilharziose dans cette région. Rapport sur une reconnaissance effectuée en janvier-février 1946 [Health Conditions in the Region of Lubilash (Belgian Congo), especially as regards Schistosomiasis a Survey made in January-February 1946] *Inst Roy Colon Belge Bull des Séances* 1947, v 18, No 2, 519-77, 3 maps & 11 figs on 2 pls

[The river Lubilash lies towards the southern part of the Belgian Congo. In this report the author gives not only the results of examinations of the people carried out by himself and his colleagues, but also the results of work done during the past few years by resident medical auxiliaries who have examined large numbers of people in their own areas. Although *Schistosoma mansoni* is not referred to by name, the whole account is concerned with the results of examinations of faeces, and, no doubt, that is the worm in question. The surveys and examinations here recorded, in spite of the limitations admitted by the author, give an impression of the prevalence of schistosomiasis which could not be so accurately conveyed by figures derived from hospital practice. They show that intestinal schistosomiasis is widespread over the whole area.]

The author remarks that although schistosome eggs are often found in routine examination of the faeces of persons who have no symptoms, it would be unwise to ignore them because the infection can lead to serious and even fatal illness. In 1939 he found that about 50 per cent of the people living on the shores of Lake Albert were infected. In 1945, on his return to the Congo, he learned that the disease was prevalent in the Lubilash area, and was requested to investigate it. In this region there was one medical man (at Katanda), and there were three medical auxiliaries in the countryside. All were working independently of each other. The infection has existed in these parts for at least 15 years,

strict control than the positive and more energetically treated. When the nasal mucus becomes positive the patient should be interned without delay. Great caution should be exercised in releasing interned patients on parole permission to go about depending on steadily improving clinical condition, disappearance of organisms from the lesions and the possibility of control outside. Tuberculous patients may be kept at home or taken into hospital if necessary until the nasal smears are negative and the more obvious lesions subside. Lastly all contacts should have a Mitsuda reaction carried out—those positive should have the privilege of visiting those interned and their friends, while the negative should attend weekly for examination.

BECHELLI, L. M. Posição dos doentes de forma tuberculóide in característica (inflammatory simplex) na profilaxia da lepra. [Status of Tuberculous Leprosy Patients in Prophylaxis of the Disease.] *Rev. 1ª seção Dermat. e Sifiloma*. 1947 July Dec. 31 No. 3, 4 468-74

This is one of a series of papers presented at the 4th anniversary of the Founding of the Argentine Association of Dermatology and Syphilology. The author pleads for less rigorous treatment of those suffering from the tuberculous or non-characteristic, non-inflammatory form of leprosy. The prevailing idea among doctors in general and the public is that leprosy is leprosy and any patient so diagnosed is a menace and should be suspect if not isolated. He shows that this view is unjust to the patient and burdensome to the State and thinks that they should be allowed to go free live with their families and carry on their occupations (with certain restrictions) under observation but unmolested so long as they remain bacteriologically negative. The actual number of lesions present has no bearing on the case. Naturally if the condition becomes clinically worse and bacterial examination reveals the presence of *M. leprae* observation should be more strict and examination more frequent. Later improvement may take place and the lesions become free from bacteria, but if the condition continues to deteriorate the patient passes from his former category and segregation and active treatment are called for. In cases under observation the leprosy reaction should be carried out from time to time. Furthermore attention should be paid not only to the patient himself but also to his contacts and associates though he himself is a burnt out case or non-infective contacts family or other may be positive.

MACDONALD A. B. Rehabilitation—the Industrial and Social Work of a Leprosy Colony. *Leprosy Review* 1948, Apr. 19 No. 7 45-55

This is an interesting account of 19 years of remarkable work in combating leprosy at Idu in Southern Nigeria, during which an agricultural colony of 3,500 leprosy patients has been built up with its village hospital, homes, home school, workshop, roads, a canal for transport, agricultural produce, court, market, farms, etc. Medical, educational, industrial, recreational, social and religious work is carried on—all a result of the efforts of Dr Macdonald and his able wife. This article should be read in the original by leprosy workers.

C. MINK & C. O. MCLELLAN. A single *Stefansky* bacillus produces leprosy. (Infection of a Rat by a Single *Stefansky* Bacillus. *Univ. Mich. L. R.* 1948 40 No. 111 421-4)

FERRO-LUZZI, G. Studio sulla bilarzio-si intestinale da *Schistosoma mansoni* in Eritrea [Schistosoma mansoni Infection in Eritrea] Boll Soc Ital di Med e Igien Trop (Sez Eritrea) 1948, v S, Nos 1/2, 5-18, 2 figs [12 refs] English summary

The first case of infestation by *Schistosoma mansoni* in Eritrea was reported by SATTA in 1934 [this Bulletin, 1936, v 33, 553, 953], the second by DIEN in 1935. Now, the disease is endemic in several places in Eritrea, notably in villages around Asmara, Saganeiti and Adi Ugru. The author names several of these. Five species of molluscs were identified there, viz *Planorbis abyssinicus*, *P. ruppelli*, *Limnaca raffrayi*, *L. africana* and *Bulinus raymondianus*. The first two of these were found naturally infested. Their biological characters, their reaction to temperature, their resistance to drying, etc are noted. Two photographs illustrate a highly infested zone near Szo olot. Children accompany animals to the streams and adults wash and bathe in them and infestation takes place via the skin and by ingestion. Preventive measures follow the usual lines: destruction of vector molluscs, careful supervision of disposal of excreta, education to drive home the ways of infestation, the dangers of infestation of and by water, and, lastly, the treatment of patients.

H Harold Scott

RAPER, A. B. Cerebral Schistosomiasis [Correspondence] East African Med J 1948 June, v 25, No 6 262-3

The author refers to the suggestion made by GELFAND [this Bulletin, 1948, v 45 721] that some cases of epilepsy appearing in adult Africans may be due to cerebral schistosomiasis. He quotes the literature to show that the two African species of *Schistosoma* are less inclined to invade the brain than is the Oriental species, and in fact the literature of cerebral schistosomiasis appears to indicate that 'up to the present *S. japonicum* holds the field as the sole proved invader of the brain' [for a full discussion of ectopic lesions in schistosomiasis see FAUST this Bulletin, 1948, v 45, 716, in his original paper, Faust quotes 56 cerebral lesions, of which 4 are attributed to *S. haematobium* and 8 to *S. mansoni* but only one of these, a *mansoni* infection, was confirmed pathologically this was a case reported personally to Faust by Carrera in Porto Rico].

The fact that such recorded schistosome infections of the brain other than those by *S. japonicum* appear to be lacking in Africa is attributed by the present author to the possibility that sufficient search has not been made for them, and he suggests that a large scale investigation in an endemic area would almost certainly be rewarded.

He then records a case of an African soldier who was brought in dead to hospital in 1942. There were many flukes in the liver and petechiae on the pericardium and peritoneum. The brain and meninges were congested, but there was no evidence of meningitis or malaria. There was what appeared to be a diffuse capillary haemorrhage in the pons, but histologically no extravasation of blood was seen, the capillaries and venules were blocked by thrombus and digestion of the brain-tissue showed *S. mansoni* eggs. A digest of the liver showed *mansoni* and *haematobium* eggs. While the characteristic granuloma surrounding ova in the brain was not present, it is likely that the man died from vascular blockage by an adult fluke or by ova. This is claimed as the first recorded case in which *S. mansoni* ova were found in the brain. The author adds that in seven other attempts to find ova by digestion in different brains the results were negative.

He also quotes a case of another African soldier, with a diagnosis of extra-medullary tumour. No ova were found in the excreta and there was no

according to reports, and a sanitary inspector of the area drew attention to it in 1942, and about the same time the cotton companies of the area noted a heavy mortality due to the condition known locally as *ditola* thought to be schistosomiasis.

Snails of various genera were found in the numerous streams of the country the most common were of the genera *Planorbis*, *L. macra*, *Lamellaria*, *Physa* and *Physa*. The species of *Planorbis* were *P. (Biomphalaria) edwardsi* or *P. (Afroplanorbis) salinarum*, and in one place the large *P. (Afroplanorbis) tanganykanus* was taken [see also this Bulletin 1947 v 44 825].

The author digresses from his main theme to discuss *ditola*, which is probably the same as the *ditola* or *madidi* described by PIERAKATS [see this Bulletin 1942, v 39 99 1947 v 44 225], and is characterized by depigmentation of skin and hair, anaemia and oedema. It is a disease of the very poor and is probably associated with severe malnutrition and hookworm infestation, but the name may be applied by the Africans to a variety of severe chronic illnesses and schistosomiasis is probably a factor in some cases.

In a table the author summarizes the findings of the three medical auxiliaries during the years 1943-45 when some 172,000 persons were examined. In 1943 the rate was 29.8 per cent. and in the two succeeding years 15.7 and 15.8 per cent. respectively.

He remarks that the true incidence must be higher probably much higher than this because as a rule only one specimen was taken from each person, and concentration methods were not used. In one area the reported figure was 69 per cent., and there were considerable differences between the rates in different places. As a rule the rates in adults were considerably higher than in children. Hookworm infestation was present in 26.6 per cent. of those examined in one large area. In certain places on the edges of the Lubilash area the incidence of schistosomiasis was much lower below 2 per cent.

The author's team which included Dr MURACK, a medical auxiliary and 5 microscopists, made a survey of 1,829 people in 9 places, examining one specimen from each person: the incidence of intestinal schistosomiasis ranged from 1.4 to 14.9 per cent. (except in one district of 50 per cent.) and of hookworm from 36 to 66 per cent. In general the infections were fairly light.

Of other diseases pulmonary tuberculosis is the most serious: it is not perhaps very common, but persons with positive sputum are reported regularly by medical men in the neighbourhood. Trypanosomiasis was found in 0.4 per cent. of 6 or 100,000 examined during 1946 (not by the author) but in one village 15 per cent. of the inhabitants were new cases. Leprosy and syphilis occur and also onchocerciasis with blindness.

There are 10 dispensaries, some built by the cotton companies, some by the government and one by a mission.

In a final note the author makes the point that schistosomiasis is a disease of adults: that up to 50 per cent. of the people are infected in some places but that the infection is usually light. His remark that in studying the Africans it is necessary to get their own illness since if the people are required to travel far to an examination centre the very sick cannot do so and some others will not. He suggests that an indigenous medical man should be found to study and deal with these remote people and to examine them all in their own place and that it should consist of 4 medical men and 6 auxiliaries (the present status of whom is not given) they report daily for pay. For the hospital and laboratory needed for such a mission an initial sum of 3,000,000 francs and the annual sum of the same amount would be necessary. In a postscript he states that the government agrees with his suggestion but that the government organizations will probably carry out the work.

FERRO-LUZZI, G. Studio sulla bilarziosi intestinale da *Schistosoma mansoni* in Eritrea [*Schistosoma mansoni* Infection in Eritrea] Boll Soc Ital di Med e Igiene Trop (Sez Eritrea) 1948, v 8, Nos 1/2, 5-18, 2 figs [12 refs] English summary

The first case of infestation by *Schistosoma mansoni* in Eritrea was reported by SATTA in 1934 [this *Bulletin*, 1936, v 33, 553, 953], the second by DIENA in 1935. Now, the disease is endemic in several places in Eritrea, notably in villages around Asmara, Saganetti and Adi Ugru. The author names several of these. Five species of molluscs were identified there, viz *Planorbis abyssinicus*, *P. rupellii*, *Limnaea raffrayi*, *L. africana* and *Bulinus raymondianus*. The first two of these were found naturally infested. Their biological characters, their reaction to temperature, their resistance to drying, etc are noted. Two photographs illustrate a highly infested zone, near Szo'olot. Children accompany animals to the streams and adults wash and bathe in them and infestation takes place via the skin and by ingestion. Preventive measures follow the usual lines: destruction of vector molluscs, careful supervision of disposal of excreta, education to drive home the ways of infestation, the dangers of infestation of and by water, and, lastly, the treatment of patients.

RAPER, A B. Cerebral Schistosomiasis [Correspondence] East African Med J 1948, June, v 25, No 6, 262-3

The author refers to the suggestion made by GELFAND [this *Bulletin*, 1948, v 45, 721] that some cases of epilepsy appearing in adult Africans may be due to cerebral schistosomiasis. He quotes the literature to show that the two African species of *Schistosoma* are less inclined to invade the brain than is the Oriental species, and in fact the literature of cerebral schistosomiasis appears to indicate that 'up to the present *S. japonicum* holds the field as the sole proved invader of the brain' [for a full discussion of ectopic lesions in schistosomiasis, see FAUST, this *Bulletin*, 1948, v 45, 716, in his original paper, Faust quotes 56 cerebral lesions, of which 4 are attributed to *S. haematobium* and 8 to *S. mansoni*, but only one of these, a *mansoni* infection, was confirmed pathologically, this was a case reported personally to Faust by Carrera in Porto Rico].

The fact that such recorded schistosome infections of the brain other than those by *S. japonicum* appear to be lacking in Africa is attributed by the present author to the possibility that sufficient search has not been made for them and he suggests that a large scale investigation in an endemic area would almost certainly be rewarded.

He then records a case of an African soldier who was brought in dead to hospital in 1942. There were many flukes in the liver and petechiae on the pericardium and peritoneum. The brain and meninges were congested, but there was no evidence of meningitis or malaria. There was what appeared to be a diffuse capillary haemorrhage in the pons, but histologically no extravasation of blood was seen, the capillaries and venules were blocked by thrombus and digestion of the brain-tissue showed *S. mansoni* eggs. A digest of the liver showed *mansoni* and *haematobium* eggs. While the characteristic granuloma surrounding ova in the brain was not present, it is likely that the man died from vascular blockage by an adult fluke or by ova. This is claimed as the first recorded case in which *S. mansoni* ova were found in the brain. The author adds that in seven other attempts to find ova by digestion in different brains the results were negative.

He also quotes a case of another African soldier, with a diagnosis of extra-medullary tumour. No ova were found in the excreta and there was no

cosinophilia. Laminectomy revealed the presence of a dense plaque of fibrous tissue compressing the cord. Removal resulted in complete recovery. Section showed that the fibrous tissue had been laid down around an adult fluke. Calcification was considerable so that the species could not be identified. Two years previously the patient had first experienced pain in the legs and difficulty in walking. Later a spastic paralysis had developed. It is suggested that the initial acute lesion had corresponded with the arrival of the adult worm in the spinal canal.

WATSON, J. M., ABDEL AZIM, M. & HALAWA, I. A. Investigations on the Antibilharzial Action of Miracid D (Miledin). *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948, July & Aug., No. 1 37-54 1 pl. (29 refs.)

Miracid D is a new drug for the treatment of schistosomiasis. It is 1-methyl-4-diethylaminoethylaminothioxanthone hydrochloride [see this *Bulletin*, 1948, v. 45 326].

In patients treated in Egypt toxic effects (if present) were slight and transient. The commonest were anorexia, nausea and vomiting. In a few cases vertigo, tremors, and tinnitus occurred. Heart, liver and kidney functions, and blood pressure were normal. There were no significant changes in the blood apart from some increase of eosinophilia. A few patients showed idiosyncrasy marked by lassitude, restlessness, insomnia, nausea, metallic taste, tingling of the skin, headache and lumbar pain.

Experiments were first carried out on mice, and gerbils infected with *S. mansoni*. The results obtained (for which the original paper should be consulted) confirmed Hikuth's reports. To kill all the worms it was necessary to give six daily doses of 40 mgm. per kgm.

The first group of 20 patients contained 14 *S. haematolum* infections, 2 *S. mansoni* infections and 4 double ones. They were given 2 doses of 0.4 gm. (7-10 mgm. per kgm.) with an interval of 3 days, and they were observed for 4-67 days. Four of the 8 *S. mansoni* infections and three of the 18 *S. haematolum* ones seemed to have been cured.

The second group contained 12 patients infected with *S. haematolum* who were given 3 doses of 0.4 gm. (stated per kgm. but presumably per person) at intervals of 3 days. They were observed for 5 to 70 days, during which period 2 ceased to pass viable ova, i.e. they may have been cured.

The third group consisted of 4 patients infected with *S. mansoni*. They were given 0.4 gm. per patient on 4 alternate days and were observed for 50 days after which time only 1 patient was still passing viable ova. They were then given a second course consisting of 0.4 gm. on 5 successive days, after which the excretion of viable ova ceased.

The fourth group consisted of 8 children infected with *S. haematolum*. They were given 0.1-0.3 gm. every twelve hours for 5-8 days. In 1 week later the urine still contained living eggs and a second course with doses of 0.1-0.3 gm. was given. Urine continued to be passed although the proportion of degenerate ones increased.

A fifth group of 8 cases was treated with miscellaneous doses and in most of them a temporary cessation of the excretion of eggs occurred.

A sixth group consisted of 14 patients who received 1.5 mgm. per kgm. every 12 hours if the uric acid was above 5 and 3 mgm. per kgm. if it was below. Treatment was continued for 5-7 days. A fortnight later all were still passing eggs.

It is concluded that Miracid D is effective against both *S. mansoni* and *S. haematolum* and that sufficient total doses administered at short intervals

sufficiently short period, but although marked improvement is apparent, complete cure is not usually attained [by the dose schedules described in the present paper]

[The patients described in this paper seem to form an earlier series than those reported by HALAWANI, *et al*, this *Bulletin*, 1948, v 45, 797] in which doses up to 7.5 gm during 8 days were employed, these doses cured 2 out of 3 patients BLAIR, HAWKING, MEESER and ROSS (in press) have found in Southern Rhodesia that when children infected with *S. haematobium* were given 10 mgm per kgm daily for 10 days, 12 out of 18 were cured (15 weeks observation), some adults tolerated doses up to 1.6 gm per person daily] F. Hawking

ATKINS, W. R. G. A Suggested Repellent for Schistosome Cercariae *J Hygiene* 1947, Dec, v 45, No 4, 468

In this brief note the author suggests that copper soaps—particularly the greasy copper oleate alone or mixed with the firmer copper stearate or palmitate—may be effective repellents for schistosome cercariae. He has not tried them but suggests that experiments could be made at those bathing beaches in America where schistosome dermatitis is common. Copper is apparently more poisonous than mercury to certain worms (not pathogenic for man). If the soaps prove to be effective, they could be used by engineers, fishermen, and others working in water. Unguentum cupri oleatis B.P.C. is 12½ per cent copper oleate in soft paraffin, it is unlikely either to irritate the skin or to be absorbed through the skin in toxic quantity. Charles Wilcocks

FIRLOTTE, W. R. A Survey of the Parasites of the Brown Norway Rat *Canadian J Comp Med* 1948, July, v 12, No 7, 187-91 [22 refs]

The author, in the Institute of Parasitology, McGill University, Macdonald College, Quebec, examined 150 specimens of *Rattus norvegicus* for parasites. The results are given in detail, and show that many species of parasites were found—the only ones of interest in human medicine, however, were *Hymenolepis diminuta*, *Capillaria hepatica* and, possibly, *Hymenolepis murina*, which were found respectively in 4, 6, and 16.5 per cent. *Capillaria hepatica* was diagnosed entirely by the finding of the characteristic eggs in the contents of the large intestine. Corro, A. de M. Contribuição para o estudo da epidemiologia do quisto hidático humano em Portugal. Sobre o grau de infestação dos cães errantes de Lisboa pela *Echinococcus granulosus*. [The Epidemiology of Hydatid Cysts in Man in Portugal. Infection Rate of Stray Dogs in Lisbon with *Echinococcus granulosus*] *An Inst Med Trop* Lisbon 1947, Dec, v 4, 285-95 [19 refs]

The English summary appended to the paper is as follows—
"Studying the epidemiology of the human Hydatid Cyst in Portugal the author determined the rate of infestation by *Echinococcus granulosus* of the street dogs at Lisbon.
'At first he refers to the number of hydatid cyst cases registered in the two largest hospitals of Lisbon, during the period 1934-1943, the mean number of cases being 35.5 (0.11 per cent of the patients) for the Civil Hospitals and 5.2 (0.16 per cent of the patients) for the Hospital of the Medical School.
'In addition the author points out that in the 150 dogs observed he found 1 infected by *Echinococcus granulosus* (3.3 per cent) and only 12 of those animals were not infected by helminths."

eosinophilia. Laminectomy revealed the presence of a dense plaque of fibrous tissue compressing the cord—removal resulted in complete recovery. Section showed that the fibrous tissue had been laid down around an adult male calcification was considerable so that the species could not be identified. Two years previously the patient had first experienced pain in the legs and difficulty in walking—later a spastic paralysis had developed. It is suggested that the initial acute lesion had corresponded with the arrival of the adult worm in the spinal canal.

WATSON, J. M., ABDEL AZIM, M. & HALAWANT, A. Investigations on the Antihelminth Action of Mircel D (Miracidin). *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948, July v. 42, No. 1 37-54 1 pl. (29 refs.)

Miracid D is a new drug for the treatment of schistosomiasis. It is 1-methyl-4-diethylaminoethyl-laminophenanthrene hydrochloride (see this *Bullet.* 1948, v. 45 526).

In patients treated in Egypt toxic effects (if present) were slight and transient. The commonest were anorexia, nausea and vomiting. In a few cases vertigo, tremors, and tinnitus occurred. Heart, liver and kidney functions and blood pressure were normal. There were no significant changes in the blood apart from some increase of eosinophilia. A few patients showed idiosyncrasy marked by lassitude, restlessness, insomnia, nausea, metallic taste, tingling of the skin, headache and lumbar pain.

Experiments were first carried out on mice, and gerbils infected with *S. mansoni*. The results obtained (for which the original paper should be consulted) confirmed Hiketh's reports. To kill all the worms it was necessary to give six daily doses of 40 mgm. per kgm.

The first group of 20 patients contained 14 *S. haematobium* infections, 2 *S. mansoni* infections and 4 double ones. They were given 2 doses of 0.4 gm. (7-10 mgm. per kgm.) with an interval of 3 days, and they were observed for 4-67 days. Four of the 6 *S. mansoni* infections and three of the 18 *S. haematobium* ones seemed to have been cured.

The second group contained 12 patients infected with *S. haematobium*, who were given 2 doses of 0.4 gm. (stated per kgm. but presumably per person) at intervals of 3 days. They were observed for 5 to 10 days, during which period 2 ceased to pass viable ova, and they may have been cured.

The third group consisted of 4 patients infected with *S. mansoni*. They were given 0.4 gm. per patient on 4 alternate days and were observed for 50 days after which time only 1 patient was still passing viable ova. They were then given a second course consisting of 0.4 gm. on 5 alternate days, after which the excretion of viable ova ceased.

The fourth group consisted of 6 children infected with *S. haematobium*. They were given 0.1-0.3 gm. every two hours for 5-6 days. In 3 weeks later the urine still contained living eggs and a second course of 0.2-0.3 gm. was given. Living ova continued to be passed although the proportion of degenerate ones increased.

A fifth group of 8 cases was treated with nine ill-timed doses and in most of them a temporary cessation of the excretion of ova occurred.

A sixth group consisted of 14 patients who received 3 mgm. per kgm. every 1 hour if the urine clearance was above 50 and 3 mgm. per kgm. if it was below. Treatment was continued for 5-7 days. A fortnight later all were still passing living ova.

It is concluded that miracid D is effective in killing *S. haematobium* and *S. mansoni* provided that sufficient total dosage is administered during

Helminthiasis

Vol 45, No 11]

Other physical signs included transient swelling and localized lymphoedema, urticaria, conjunctivitis, and mental manifestations, mainly anxiety states. "Filarial fever" was not reported in early cases. In a few instances abscesses were reported, these were presumed to be filarial in origin. There was no evidence of sexual dysfunction.

"Attacks" were nearly always short, 3 to 5 days in duration, in many instances the signs and symptoms had disappeared in a matter of hours, and very rarely they lasted for longer than 2 weeks [except presumably the mental symptoms]. Relapses were relatively common, they were precipitated by hard exercises, fatigue, and hot climate, they occurred up to two years after infection. Lymphatic lesions in the experience of most writers persisted for some time after the return of the men to the United States, but having eventually subsided were seldom found after 20 months to 3 years, according to different observers, from the time the subject left the endemic area.

There are reports of the finding of microfilariae in the blood in 20 cases only; this includes one instance in which positive findings in 8 cases were reported, whereas 13 authors report no positive findings in a total of 364 biopsies, adult worms or microfilariae were found in 78 (22 per cent). The adults were all identified as *W. bancrofti*. Bacterial cultures of biopsies were almost without exception negative.

The white cell count averaged 9,000 per cmm and eosinophilia occurred in one-half to two-thirds of the cases, averaging 850 per cmm. The blood sedimentation rate was usually unchanged.

Positive intradermal tests varied from 35 per cent to 91 per cent but most writers reported percentages above 80. *Dirofilaria immitis* was used for preparing the antigen in most instances. False positives were uncommon, usually of the order of 5 per cent, the test was only considered positive if both immediate and delayed reactions were noted. The reaction appeared early, usually prior to the first symptoms. Antigens made from other filarial worms, e.g., *Setaria equina*, *Litomosoides carini*, and the microfilaria of *W. bancrofti*, were also used with very similar results. Tests with antigens prepared from other nematodes, e.g., *Ascaris*, gave less satisfactory results.

There is a detailed description of the pathological findings in biopsies from various sites including the epididymis, spermatic cord, testis, lymph nodes from various places, with and without worms, and lymph vessels. These are also presented in tabular form and are illustrated by beautiful photomicrographs. In ten lymph nodes adult worms were found, in 23 characteristic histological changes were found in the absence of worms, and in 24 others neither worms nor characteristic lesions were found. The following summary of the histological findings is quoted —

"It is interesting to make a comparison of the tissue reactions associated with adult worms, and with microfilariae. In the former there is precipitation of strongly acidophilic material about the worms with necrosis of tissues, exudation of eosinophils, plasma cells and lymphocytes, and proliferation of macrophages and reticular fibers. In the latter there is no necrosis and the precipitate around the microfilariae, when it occurs, is amphoteric. Edema is conspicuous and the exudate is comprised chiefly of eosinophils. Macrophages and giant cells, although present, are not numerous and there is only slight reticular hyperplasia."

With reference to pathogenesis, two relevant quotations from the "Discussion" are given below —

"As a result of the war experience clear evidence has accumulated that early filariasis is due solely to *W. bancrofti* and is not caused by bacteria or conditioned by their presence. Even after many months bacteria have not entered into the picture. Much other evidence indicates that *W. bancrofti* is

OKY OKM BIK. Een geval van Ileus door Ascariëden veroorzaakt. (A Case of Intestinal Obstruction caused by *ascaris*.) *Med Maandblad Batavia* 1948 July 1 No. 74 488-9.

The English summary appended to the paper is as follows:—

"Description of a case of intestinal obstruction due to *Ascaris lumbricoides* in a 3 years old Indonesian girl.

"The mass of worms which was located in the last 30 cm. of the ileum, near the ileo-caecal valvula, consisted of 68 *Ascaris lumbricoides* (27 male 39 female) and was removed by operation. Diagnosis as to the cause of obstruction could not be made before operation.

WARTMAN W. B. Filariasis in American Armed Forces in World War II. *Medicine* 1947 Dec. v 28, No. 4 333-84 33 figs. [55 refs.]

Pathological material, all from biopsies, was collected from every available source for the U.S. Army Institute of Pathology: this forms the basis of the report. The clinical picture is drawn from numerous published reports and refers only to soldiers, sailors and marines in the U.S. services.

The patients were nearly all young men between the ages of 18 and 24. Most were infected in the Samoan Islands the number from Walu Island being unusually high. A few were infected elsewhere (e.g. in the Solomon Islands). The average time spent in an endemic area was 11 months and the shortest time was one month. The usual incubation period was from 3 to 18 months but adult worms were recovered in biopsy material within 3 months of the first exposure.

The onset was usually manifested by painful swelling of the scrotal contents, arms and legs, either singly or in combination. Frequently the affected parts were swollen red and itched, and at times wheals were noticed. Although headache, backache, fatigue and nausea were common, other constitutional symptoms such as fever, chills and malaise were unusual. Subjective symptoms were prone to develop suddenly, were mild to moderate in severity, often fleeting, and were characterized by remission and exacerbations. Often patient had no symptoms at all and the disease was accidentally discovered during the course of a routine physical examination. In evaluation of the symptoms it should be remembered that they were tabulated from statements made by the patients themselves, many of whom were suffering from built fatigue or had considerable anxiety or even fear about the outcome of the disease: the statements were no doubt influenced by these factors.

The most frequently encountered physical signs were lesions of the genitalia. Of these the commonest were funiculitis, epididymitis, orchitis and scrotal oedema and inflammation. If drainage and varicose were also but very common, but chylous hydrocele and elephantiasis were not reported.

Lymphadenitis was the next most constant sign: the commonest groups were the inguinal, femoral, axillary and parotid. In few instances the cervical glands were involved and rarely the subclavicular, popliteal and pectoral. Few other reports generalized lymphadenitis.

Retrograde lymphangitis was common but far less common than lymphadenitis. In which it was usually associated, occasionally it was not associated, alone. The same as was mainly involved. There was erythematous reaction and the associated pain was minimal.

This observation confirms previous experiments and indicates that *Culex pipiens* var *pallens* is a poor intermediate host of *W. malayi*. L E Napier

BROSIOUS, O T, THOMAS, Esther E. & BROSIOUS, Barbara Capillaria hepatica A Case Report Trans Roy Soc Trop Med & Hyg 1948, July, v 42, No 1, 95-7

Record of the case of a woman in Panama, 28 years of age, suffering for 4 days from very acute epigastric pain at short intervals accompanied by nausea and once by vomiting. In the stool were ankylostome and *Capillaria hepatica* ova. The family lived largely on "wild meat", including conejo pintada, a small amphibian rodent, and venison and birds, she was very partial to liver of the former. She denied eating peccary (an animal infested in nature by *Capillaria hepatica*) or monkey (the red spider monkey, *Ateles geoffroyi*, and the white-faced monkey, *Cebus capucinus imitator*, are both hosts of the *Capillaria*). The pain was relieved by morphine, oil of chenopodium was given for the hookworm, subsequent stool examinations failed to reveal any ova of *Capillaria hepatica*. H Harold Scott

ERHARDT, A E Kritischer Beitrag zur Behandlung der Oxyuriasis [Critical Review of the Treatment of Enterobiasis] Med Klin 1947, Dec, v 42, Nos 23/24, 859-61 [23 refs]

The author refers in this brief article to more than a score of vaunted remedies for *Enterobius* infestation. In assessing their value, one must be careful to distinguish relapse which may occur up to 8 weeks after the remedy is used (and implies failure to eradicate) and reinfection, indicated by appearance of ova in the stools later than this. He speaks most highly of Lubisan, resorcin-mono-butyl-ether-diethyl carbamate, which, according to report, succeeds in about 75 per cent of cases. For many drugs of repute—helminal, butolan, santonin, ascaridol, gentian violet, among others—he has not a good word to say. He concludes that up to the present there is no absolutely reliable remedy, that all we can do is to treat symptoms, apply measures to prevent infestation or re-infestation, and that in time the infestation will clear up of itself. [Not very helpful, but probably quite true. A useful survey.] H Harold Scott

DEFICIENCY DISEASES

DRILL, V A & LOOMIS, T A Production of Functional and Fatty Changes in the Liver by a Chronic Vitamin B Complex Deficiency and Interrelationships with Protein Intake J Nutrition 1948, Mar 10, v 35, No 3, 333-48, 6 text figs & 8 figs on 1 pl [21 refs]

Liver damage has been produced in animals both by diets deficient in protein and by diets deficient in vitamins of the B complex. Often, however, the experimental conditions have not made it possible to distinguish between the effects

the etiologic agent such as the demonstration of adult and larval parasites accompanied by significant lesions in involved tissues the results of intradermal testing and the clinical manifestations of the disease."

"Many clinical manifestations of early filariasis such as blotchy redness of the skin absence of severe constitutional symptoms blood eosinophilia, and rapid appearance and disappearance of symptoms, are suggestive of hyper sensitivity. During attacks of acute lymphangitis in one extremity there is not infrequently enlargement of lymph nodes in distant parts of the body such as the neck, groin or opposite extremity. The high incidence of positive skin tests desensitization, passive transfer experiments and reproduction of some of the characteristic signs and symptoms by intradermal injection of a suitable antigen can all be explained on this basis.

[The paper as a whole constitutes a most important document on the early manifestation of filariasis and should be studied in the original.]

CHEN H. C. A Note on the Filaria Survey in Fukien Province. *Lingnan Sci J* 1948, v 22, No. 1/4 85-92, 1 map. [12 refs.]

A questionnaire on the incidence of elephantiasis in Fukien province was sent out. The disease was reported in 38 *hsien*s in 14 of which it was especially prevalent. From 25 *hsien*s it was reported as absent.

Microfilarial surveys were carried out on a number of places in the province blood specimens were taken between 9 p.m. and 11 p.m. The findings in the different locations are discussed in detail. In Foochow hospital patients in whom the infection was suspected were examined and 40.1 per cent. of 207 patients were found infected. Many of these came from outside Foochow. In about one-third of the cases *M. malays* was found. In other places unselected prisoners, students or members of volunteer corps were examined. The microfilarial incidence varied from 30.0 per cent. (Changpu) to nil (Yungai and Shashien). Incidences above 10 per cent. were found in Futsun (29.1 and 19.4 per cent.) Putien (14.5 per cent.) and Haileng (1 per cent.).

The correlation between microfilaraemia and elephantiasis is not discussed, but the two *hsien*s showing no microfilaria do not appear in the list of those reporting elephantiasis and of the three *hsien*s showing the highest microfilarial incidence two appear in the list of those with especially prevalent elephantiasis.

M. malays was diagnosed in about one-fifth of the positive cases in the non-hospital groups this infection is apparently widespread in the province.

A map shows the distribution of filarial infection as occurring along the coast-line and in the riverine areas.

HU S. M. H. Notes on the Experimental Infection of *Culex pipiens* var *pallens* Coq. with *Microfilaria malays* Brug. *Lingnan Sci J* 1948, v 22, No. 1/4 79-83.

In Shanghai between September 13th and 14th 1940 *Culex pipiens* var *pallens* were fed in three batches on a patient heavily infected with *M. malays*. The average blood microfilaria counts during the times of feeding varied between 323 and 5.1 microfilariae per cmm. of blood.

In a total of 247 mosquitoes dissected between the 6th and 30th days after the infective feed, filarial larvae developed to the infective stage in only 5 (2.03 per cent.) and in each case there was only very few larvae. In 20 other mosquitoes immature larvae were found all of these except one were dead or completely encapsulated, and the remaining one had reached the second stage.

This observation confirms previous experiments and indicates that *Culex pipiens* var *pallens* is a poor intermediate host of *W. malayi* L E Napier

DEFICIENCY DISEASES

DRILL, V A & LOOMIS, T A **Production of Functional and Fatty Changes in the Liver by a Chronic Vitamin B Complex Deficiency and Interrelationships with Protein Intake** *J Nutrition* 1948, Mar 10, v 35, No 3, 333-48, 6 text figs & 8 figs on 1 pl [21 refs]

Liver damage has been produced in animals both by diets deficient in protein and by diets deficient in vitamins of the B complex. Often, however, the experimental conditions have not made it possible to distinguish between the effects

of these two deficiencies. One reason for this is that the appetite is often unimpaired, and with reduced food consumption there is inadequate intake of all nutrients. The experiments reported here were designed to overcome these difficulties. A chronic deficiency of the whole vitamin B complex was produced in dogs—the food intake was measured, and a control group was pair fed, but given an adequate vitamin supplement. In this way the effect of inanition *per se* could be determined. To test the possibility of an interaction between protein and B vitamins in their effects upon the liver the experiments were carried out at two levels of protein intake—normal (20 per cent. casein) and high (41 per cent. casein). Liver function was studied by serial measurements of bromsulphthalein retention and of serum phosphatase. These tests were chosen because they are in common clinical use. A single biopsy of the liver was made in each animal after about 30 weeks.

On the high protein diet the vitamin-deficient animals had reduced appetite and lost weight. No histological or functional changes were found in the liver. In one dog there was proliferation of the capsular epithelium and crescent formation in the renal glomeruli. On the 20 per cent. casein diet vitamin deficiency produced an increase in bromsulphthalein retention and serum phosphatase concentration. Biopsies of the liver taken at the 33rd week showed a moderate degree of fatty infiltration.

[The photomicrographs of these biopsies show a striking resemblance to that published by SERRELL in his description of the "yellow liver" of anbulavivorous in the dog (SERRELL, 1933 *Nat Inst Health Bull* No. 16, p. 23).]

After the biopsies the dogs were given an adequate vitamin supplement but kept on a restricted food intake. When they were killed 10 weeks later the livers were normal. In the inanition controls there were neither functional nor histological changes in the liver.

[These experiments have an obvious bearing on problems of human disease that have been discussed in recent numbers of this *Bulletin*. But it must always be remembered that, in the field of nutrition, the results obtained on one animal cannot be applied without reserve to another. It would be dangerous to conclude that in man avitaminosis can cause liver damage in the presence of a normal supply of protein. The authors do not imply this, but the discussion they give of their results is confusing.]

Although in the dog both protein- and vitamin-deficiency may cause liver damage, the former seems to be the more powerful factor. In dogs given a very low protein diet with adequate vitamin, liver damage was much more severe and rapid in onset than that described above. (LIE & FREEMAN *Am J Physiol* 1948, 145, 646).] J. C. HAZEL

FRASO-LI ZZI G. Studio sui fenomeni di malnutrizione in Lente a. Nota IIIa. Ricerche sperimentali su diete a base di dura (Andropogon sorghum) di talli (Eragrostis abyssinica) e di orzo. Nutrition Studies in Eritrea. III. Experimental Research with *Andropogon sorghum* Eragrostis and Barley. *Bull Soc Ital di Med Igiena Trop* (N. 2, Eritrea) 1948, 1, 8, Nos 1-2, 54-61.

The numbers of animals subjected to experiment—white (1 of 20-30) gm. weight—were few from which to draw and deduct any. Five (1 male 4 females) were fed on tall (1 male 4 females) only, five (5 males 4 females) on dura (*Eragrostis abyssinica*) only, and 4 males on barley only. 19 animals altogether. 10 lived for 1 month, nine for 9 months, one for 6 months, and two for 3 months only, one escaped after 6 months. Eleven were killed in the course of the investigation, 8 died of dysentery. All showed lack of weight and interference with fertility.

The author came to the conclusion that the effects were not the result of avitaminosis but of protein deficiency, especially amino-acids, in other words, the proteins in these pulses are of "poor biological value", and unable to maintain a satisfactory nitrogen balance. Control animals receiving fresh vegetables in addition showed no signs of malnutrition.

H Harold Scott

ALTMANN, A. The Syndrome of Malignant Malnutrition (Kwashiorkor Infantile Pellagra) Its Conception as a Protein Deficiency and Its Treatment with Skimmed Lactic Acid Milk. *Clin Proc Cape Town* 1948, Jan, v 7, No 1, 32-53 [84 refs]

Thirty cases are described of kwashiorkor in Bantu babies and children varying in age from three months to six years. They presented the characteristic clinical picture—loss of weight, dermatosis, lesions of mucocutaneous junctions, depigmentation of the hair, oedema, hypoproteinaemia, and normocytic anaemia of moderate severity. Although all cases had the typical rash, the author believes that this and other signs of vitamin deficiency are not essential features of the disease, they are not always present, and bear no relation to the severity of the individual case. He contends that the main cause of the syndrome, which is in no way peculiar to the Bantu, is lack of protein and lack of calories, and that it closely resembles the condition known to paediatricians in Germany as *mehlnährschaden*, or "flour-feeding injury".

In kwashiorkor, as in *mehlnährschaden*, there is a history of feeding on a mainly carbohydrate diet. In both there is oedema and fatty liver. The classical descriptions of *mehlnährschaden* mention muscular rigidity, which is a not uncommon feature of kwashiorkor. In some cases there is a reddish-brown pigmentation of the skin, which may be analogous to the kwashiorkor dermatosis. If kwashiorkor, like *mehlnährschaden*, is a result of protein deficiency, it should be cured by a high protein diet. Dr Altmann points out that "when using a therapeutic formula in nutritional disorders of babies, it is not only important to choose the correct formula, but also to apply it correctly". The food he suggests is lactic acid skimmed milk. This was given in small quantities at first, increasing daily until 30-35 oz were taken in 24 hours. On this treatment it was found that the frankly oedematous patients did well, there were 22 cases of this type, and all recovered. The prognosis was much worse in those who were dehydrated or atrophic [the terms seem to be used synonymously]. Of 8 such cases, 5 died. No details of post-mortem findings are given.

The paper ends with a long and fully documented discussion, devoted mainly to oedema, the significance of fatty liver, and the results of treatment. Oedema is not an essential part of the syndrome, since the most serious cases are those in which it is absent or minimal. Nor is fatty liver pathognomonic of kwashiorkor since it is found in infants dying of many other conditions. Even when fatty infiltration is present, there is no evidence that it causes serious functional impairment or that death occurs from liver failure. [Recent work on kwashiorkor is in agreement with Dr Altmann's main conclusions—that the condition is a result of protein deficiency, that the signs of avitaminosis are inessential complications, and that there is a good response to treatment with milk alone.] The comparison with *mehlnährschaden* has been made by others, but not so fully. It is of value, because it lifts kwashiorkor out of the realm of purely tropical diseases, and brings it into relation with the existing body of knowledge about the nutritional disorders of infants in temperate countries. This knowledge is far from complete, and will in turn be amplified by the work on kwashiorkor. If this position is accepted, it is only

logical to apply to kwashiorkor the classical principles of feeding evolved by paediatricians for the treatment of infantile malnutrition. Dr Altmann is the first to do this explicitly.

Some of his conclusions on other points are, perhaps, open to criticism. He distinguishes between oedematous and dehydrated cases—reference to his tables shows that in all the dehydrated cases oedema was said to be present, comparable in severity and extent to that found in the waterlogged patients. There was also an equal reduction in the serum proteins—in 4 out of 6 dehydrated cases the total protein was less than 4.0 gm. per cent. It therefore seems reasonable to look upon this dehydration not as a difference in kind, but as a complication, which, as in other diseases of infancy, is of grave omen.

The contention that liver function is not affected by the presence of fat cannot be accepted without reserve. Experimentally functional impairment has been found in rats (MACLEAN *et al.* *Brit. J. Exper. Path.* 1937 v 18, 345) and in dogs [above] with fatty livers. It has also been reported in human infants since Dr Altmann's paper was published [WATERLOW *this Bulletin* 1948 v 45 774]. There are several observations in the literature of sudden death in coma in kwashiorkor which are suggestive of death from liver failure [see HUGGINS *ibid* 1948 v 45 768].

ALTMANN R. J. & STOLLERMAN G. H. The Course of Beriberi Heart Disease in American Prisoners-of War in Japan. *Ann. Intern. Med.* 1948, May v 28, No. 5, 949-8, 3 figs. [28 refs.]

FLACHS A. Nicotinamidetherapi ved pellagros diarrhoe ("pellagra sine pellagra"). [Nicotinamide Treatment of Pellagrous Diarrhoea, "Pellagra sine Pellagra."] *Nordisk Med* 1948, Aug. 15 v 39 No. 33, 1507-9 [25 refs.]

The English summary appended to the paper is as follows:—

"22 cases of diarrhoea observed in the medical department of the Old People's Home at Copenhagen were treated with nicotinamide. All the cases had been treated previously with the ordinary obdipants without effect. None of the patients except 2 had had cutaneous pellagrous manifestations. In 17 cases the nicotinamide therapy proved successful. In one of the cases that did not respond to the specific therapy, autopsy revealed a cancer of the colon. A dose of 15-30 mg. nicotinamide per day was given and effects could be observed after 1-3 days. A case of arbovirus leucosis is described in which treatment with lactoflavin led to an outbreak of pellagrous diarrhoea and the author points out the antagonistic action of the vitamins of the B group."

SPRUE

LONGS Elizabeth M. The Blood and Bone Marrow in the Sprue Syndrome. A Study of 63 Cases. *Edinburgh Med. J.* 1948, May v 55 No. 5 202-92 [19 refs.]

From a review of the literature it is evident that the frequent occurrence of megaloblastic anaemia among cases of tropical sprue has been established. On the other hand, the blood picture in the sprue syndrome as met with in Britain is much less well-defined.

Sixty-three cases of the sprue syndrome have been studied. Seventeen could be classified as tropical sprue, 27 as non-tropical sprue and 19 as coeliac disease. It appears clear that the adult sprue syndrome is typically associated with

macrocytosis of the erythrocytes which may be accompanied by anaemia, but sometimes not. This statement applies equally to tropical as well as non-tropical sprue. The difference between them is one of degree, as the tendency to anaemia and macrocytosis is greater in the non-tropical group, but the bone marrow picture is characteristically megaloblastic when there is a marked degree of macrocytic anaemia. Occasionally this megaloblastic reaction may prove completely refractory to parenteral liver therapy, though usually this will improve the blood level and change the marrow picture either to the normoblastic or intermediate state. It would appear that the administration of liver results in a partial maturation of the megaloblasts. The process is, however, not complete and stops short of a complete transformation to the normoblastic state. The erythrocytes which result are reduced in numbers and are larger than normal, a fact which explains the persistent macrocytosis so characteristic of this condition. It is therefore suggested that some other factor is necessary for the complete restoration of normal erythropoiesis, the nature and identity of this factor is unknown. In some cases, the factor might be folic acid, but in others the macrocytic anaemia persists despite its prolonged administration.

Macrocytic megaloblastic anaemias are extremely uncommon in childhood, so that it is not surprising to find among children with coeliac disease that the anaemia is characteristically of the hypochromic microcytic variety. In this case the marrow is normoblastic and appears capable of producing adequate numbers of erythrocytes, the defect being in their haemoglobinization, but the cases failed to respond to the therapeutic administration of iron—a phenomenon which could be explained either by failure of absorption of iron from the bowel or by failure on the part of the marrow to utilize it.

In this series one patient with coeliac disease responded excellently to intravenous injection of 'Ferrivenin' (a proprietary preparation of saccharated oxide of iron). Therefore it is suggested that parenteral iron therapy may prove of great value in the cure of the iron-deficient anaemia of coeliac disease which persists despite prolonged oral administration long after the signs and symptoms of the syndrome have disappeared.

The two most urgent problems for solution are (1) the nature of the factor required for complete restoration of normal erythropoiesis in cases of sprue partially refractory to liver extract and folic acid, and (2) the mechanism underlying the failure of hypochromic anaemia of coeliac disease to respond to iron.

VENOMS AND ANTIVENENES

BOGULT, P. Venins de serpents et antivenenes [Snake Venoms and Antivenenes]. Préface du Professeur Jules BORDET. Collection de l'Institut Pasteur 157 pp, 12 text figs & 4 figs on 2 pls 1948 Paris. Editions Médicales l'Innovation [400 fr]

In this interesting memoir the author summarizes the results of researches on snake venom carried out in France and other countries during recent years

After a brief historical account of the effects of snake bite, the venoms of vipers and colubrids are dealt with generally (opisthophis excepted). The mechanisms of biting and the secretion of venom are briefly discussed and there is a very clear account of the present knowledge concerning the chemical structure and enzyme content of venoms and of their action on the enzymes. The action of physical and chemical agents on venoms is also described, and there are chapters on natural and acquired immunity, the treatment of snake bite and the therapeutic uses of venom. There is a short bibliography.

One chapter is of special interest. Therein the author has attempted to classify venoms according to their physiological and pathological properties. After tabulating variants of these properties such as coagulant, anticoagulant, haemolytic, etc. he groups venoms into four categories, namely: (1) Curarising anticoagulants (type *Naja tripudians*), (2) Curarising coagulants (type *Demansia textilis*), (3) Haemorrhagic anticoagulants (type *Buteo rufus*), (4) Haemorrhagic coagulants (type *Bothrops russellii*). Group 1 contains the venoms of most of the colubrids of Africa and Asia and some of those of Australia. Group 2, the venoms of the Australian colubrids. Group 3, those of the viperines of Africa and America. Group 4 the venom of the viperines of Europe, America, Asia and of the genera *Echis* and *Crotalus* of Africa.

The author points out the close similarity between the toxic actions of venoms and those of certain bacterial toxins with which the venoms appear to form families *naturelle* in spite of their differing chemical and antigenic structures.

The book is extremely well arranged and clearly written and can be thoroughly recommended to all who are interested in snakes and snake venoms.

SARKAR, N. H. Existence of a Cardiotoxic Principle in Cobra Venom. *Ann. Biochem. & Exper. Med.* 1948, Jan. Feb. v. 8, No. 1-2, 112, 17 figs. [18 refs.]

The author and others had previously observed that isolated toad heart was brought to a stop in systole by perfusion with crude cobra venom, but not by the various products isolated from the venom such as the haemolysin. In the experiments described in this paper the author records the effects of perfusion of crude venom, haemolysin, neurotoxin and choline-esterase upon isolated toad and kitten hearts and the action of crude venom on the circulation of cats (with and without artificial respiration). The author concludes that cobra venom has a definite toxic action on the heart and that neurotoxin, choline esterase and haemolysin have not. The action of this cardiotoxic factor which the author has labelled cardiotoxin 19 and claims to have isolated in a pure and concentrated form was further examined in isolated toad heart and intact anaesthetized cats. At a concentration equal to half the effective concentration of crude venom the isolated heart was stopped in systole. Intravenous injections of a dose of cardiotoxin (equal to half the effective dose of crude venom) produced gradual fall of blood pressure to zero and loss of respiration. Artificial respiration failed to revive the animal and the heart was eventually stopped in systole.

In a general introduction to his paper the author states that in India 5000 to 30,000 deaths occur every year from snake bite and claims that considerable numbers of deaths occur from the same cause in other countries including Africa and Australia. No author is responsible for the latter statement which is merely opinion to one's doubts. It is difficult to accept the author's conclusions on the evidence submitted in the paper. For instance although he states that haemolysin has no effect on the isolated heart he records Table IV

that a dose of non-crystalline haemolysin in a concentration of 1 in 50 caused a perfused toad's heart to stop in systole, whereas the same dose of crystalline haemolysin had no apparent effect. Table VI is headed "Amount of cobra venom required for the cardiac failure as indicated by the fall of B P to zero mm (artificial respiration being used)". In a condition in which shock frequently predominates, measurement of cardiac failure in terms of fall of blood pressure cannot be reasonably accepted. However, at high concentrations of crude venom his published charts indicate some action on the heart, and the work should obviously be repeated more carefully in order to ascertain whether this effect is in fact due to a specific cardiotoxic principle.] B G Macgregor

TRETHEWIE, E R & DAY, A J The Influence of Heparin on the Toxicity of Australian Snake Venom. *Australian J Exper Biol & Med Sci* 1948, Jan, v 26, Pt 1, 37-43, 2 figs

Other workers have shown that heparin significantly reduces the toxicity of the venoms of the *Echis carinatus* and *Vipera russelli* [this *Bulletin*, 1947, v 44, 846], both of which have coagulant effects. The authors report the results of an investigation of the effects of heparin on the thrombotic activity of the venoms of two Australian snakes, *Notechus scutatus* and *Pseudechus porphyriacus*. Tiger snake (*Notechus scutatus*) venom was injected subcutaneously into guinea-pigs in about double the LD₅₀ dose and heparin was injected immediately afterwards and thereafter daily. Control series were injected with venom alone. Venom of *Pseudechus porphyriacus* was injected into mice by means of a similar technique. In both sets of animals the death time was measured. Heparin did not affect the toxicity of either venom, but prolonged the death time in heparinized animals. The authors point out that "in Australian snake venoms there appear to be three distinct principles, namely, formation of lysolecithin, a thrombotic and a neurotoxic principle". They suggest that these three elements may act at separate times, the thrombotic and lysolecithin effects acting first. Heparinization might inhibit the thrombotic effect and allow the more slowly acting neurotoxic principle to kill, so lengthening death time. Alternatively, the three elements of the venom might act together, the heparin, by minimizing one of them, might extend the period of life. After doses near the LD₅₀ heparin did not allow survival but merely prolonged life. The authors suggest that heparin might be useful therapeutically in that the life of persons suffering from black-snake or tiger-snake bite might be prolonged by its administration so that other forms of treatment of known value might be given more opportunity to act. EARLE K V Injuries produced by Tropical "Water-Beetles" *Trans Roy Soc Trop Med & Hyg* 1948, July, v 42, No 1, 101-4, 2 figs [10 refs]

In Ecuador three species of water-beetles are found *Lethocerus campostus* up to 3½ inches in length, *L. annulipes*, to 2½ inches, and *Belostomatidae*, to 1 inch. They live on aquatic insects, fish and frogs, and may attack and kill birds. They are attracted by bright lights and in the rainy season may leave the ponds, sewers and marshes for the land and are found congregated at the base of lamp-posts. They do not as a rule bite man unless handled. The bite of the largest is painful and causes at first blanching, then swelling, redness

and throbbing these usually clear up in 24 hours but occasionally cellulitis and abscess follow. Treatment is symptomatic ammonia locally in the early stages later if there is suppuration, sulphonamides or penicillin. The existence of poison glands is uncertain there are two pairs of glands lying lengthwise along the oesophagus and, just above the beak, the cephalic glands, the homologues of the maxillary glands. Whether any of these produces venom has yet to be determined. The ventral and dorsal aspects of the largest water beetle the first named, are well reproduced in two photographs.

DERMATOLOGY AND FUNGUS DISEASES

AGUIRRE PEQUEÑO E. & GONZALEZ, R. E. Mal del pinto. (Bibliografía)
[Bibliography of Pinta.] *Medicina*. Mexico. 1948, July 10 & 28, No. 559
—57-313

This immense compilation occupies more than 50 pages and is evidence of very great industry and patience. After a brief introduction, the authors give a lengthy list of synonyms for this disease, shown topographically for different American countries. The bibliography is then presented in alphabetical order of authors and thus occupies 18 pages—a chronological bibliography from the year 1525 to 1948 takes another 18 pages—then follow bibliographies relating respectively to geographical distribution, aetiology, epidemiology, inoculation experiments, possible vectors, clinical features, pathology, differential diagnosis, serology, and treatment. Further short bibliographical references deal with historical work, monographs, theses, general papers, books and commentaries—the last named includes references to *Pinta* in this *Bulletin* from 1913 to 1948. The very large number of contributions to the literature by the senior author himself is additional evidence of his wide knowledge and experience of his subject.

This paper constitutes a very useful conspectus of the literature of pinta.

DELAMATER, E. D. Technique and Identification of Fungi of Medical Interest.
Amer. J. Clin. Path. 1948, Mar & 18 & 3, 233-48, 3 figs. [13 refs.]
[Summary appears also in *Bulletin of Hygiene*]

The pathogenic fungi which may occur in various human materials are tabulated and methods for direct observation and culture are briefly described. The indiscriminate use of the so-called 'abourated' medium is criticised. Though this medium is suitable for primary isolation of the dermatophytes and of *Candida*, the use of cornmeal agar, dextrose nutrient agar, blood agar and thioglycollate broth for other fungi is described. Bacterial contamination may be prevented by penicillin-tryptocain medium but it is not possible to inhibit the growth of saprophytic fungi. The mouse is a valuable diagnostic animal for routine use and, while it may be essential in the isolation of *Sporothrix* and *C. immitis*, it is useful also in determining the diagnosis of infections by other fungi.

The paper concludes with a short description of each of the important disease-producing fungi and is illustrated by 3 plates. The author states that actual culture and identification of the dermatophytes is not essential to still the diagnosis of the treatment of the mycotic diseases and that the simplified method used by Cantani and others for the identification of *Candida* with its own series of 11 formulae may be of value.

simulated by minute budding cells of *Candida albicans* in smears The differentiation of *Actinomyces bovis* from *Nocardia asteroides* is clinically important in view of their different drug sensitivities R W Riddell

SNYDER, B L & ROGERS, G K Disseminated Coccidioidal Granuloma (Case Report) Arizona Med 1948, Mar, v 5, No 2, 33-7

The disseminated form of infection by *Coccidioides immitis*, which carries a mortality rate of more than 50 per cent, constitutes only 0.2 per cent of all cases of coccidioidomycosis The primary, or pulmonary, form is prevalent in Arizona and is usually non-fatal

The case history is described of the disseminated disease in a young adult white male who had resided in Arizona for 3 years He complained of fatigue, cough, fevers, muscular aches and loss of weight, and examination revealed an upper lobe pulmonary lesion Three months later cutaneous coccidioidomycosis had developed over the chest and face and grew progressively worse The coccidioidin test and specific serological reactions were negative Raised intracranial pressure led to death of the patient about one year after his initial hospital attendance The cerebrospinal fluid had shown an increase in protein and lymphocytes, but culture was negative

A wide distribution of coccidioidal granulomata was demonstrated at necropsy, the liver was not obviously involved Cerebrospinal lesions were limited to the meninges, where fungus spherules tended to be larger and more actively proliferating than elsewhere The clinical and pathological features of the cutaneous disease are discussed R W Riddell

HARR, J. Studies in Tropical Ulcer. Part I. The Origin of an Epidemic. *J. Trop. Med. & Hyg.* 1948, Mar. v. 51 No. 3 47-53 + 67x. [7 refs.] Part II. The Aetiology of Tropical Ulcer *Ibid.* Apr., No. 4 7-81 [18 refs.] Part III. The Insect Vector *Ibid.* May No. 5 99-102. [12 refs.] Part IV. The Treatment of Tropical Ulcer *Ibid.* June No. 6 119-28. [28 refs.]

I. In this paper the term 'tropical ulcer' is reserved for acute ulcers having a phagadenic tendency and which are characterized clinically by a foul smell and an adherent slough overlying a soft granulomatous base that bleeds easily. Bacteriologically the fusiform bacillus is constantly found whatever other organisms may be present.

The Tingri district in Assam, in which the work reported was carried out covers an area of about 144 square miles, and is almost absolutely flat, the soil being the usual alluvial silt of the Brahmaputra valley. In it are found 201 estates, areas of forest and scrub jungle, rice land, and scattered native villages. The population consists chiefly of aboriginals from Central India with some Nepalese and Assamese in the villages. November to February are dry and comparatively cold, March and April are warmer with scattered rainfall, and May to October hot and humid with a fairly high rainfall. The average yearly rainfall is about 95 in., of which about 85 in. fall during the latter period. Shade temperatures are not above 100 F. but humidity percentages of 90 and over are common.

Up to 1941 tropical ulcer was very rare in this district. About 1941, many of the labourers were sent to the outfields for jungle clearing and to various military works.

The author gives a table of the incidence of the disease in 1948 in 13 estates on which he worked. Out of a total estate population of 20,000 1,101 cases (5.52 per cent.) were met with but the condition was also widespread in the neighbouring villages. From a study of the incidence on tea estates it was noticed that an appreciable period elapsed between the appearance of the disease in one line and its spread to another. Study of the figures for 13 estates in each month of 1948 showed that during the 4 cold dry months (November to February) the incidence was nil. There was therefore no carry-over of cases from one season to the next and maintenance of the infection cannot be blamed on isolated sporadic cases during the cold months. All authors appear to agree that natural or acquired immunity does not occur in tropical ulcer.

The paper is illustrated with five tables and four figures and the tables include figures for the incidence of tropical ulcer from 1947 to 1948 inclusive.

II. The author considers that (1) Tropical ulcer is a pyogenic disease associated with infection by the fusiform bacillus. Under ordinary conditions only man is susceptible; experimental infection of the ordinary laboratory animal having been found impossible. One observer however states that the Nigerian hedgehog is susceptible (SMITH, *Trop. Res. Soc. Trop. Med. & Hyg.* 1936 v. 30 259). There is no evidence that a filterable virus is responsible (this *Bull.* 1946 v. 43 58).

(2) The condition is confined to warm countries and to seasons of moderate heat and rainfall. The disease disappears under conditions of extreme heat and drought, and excessive wetness and rainfall.

Tropical Ulcer

Vol 45, No 11]

(3) Tropical ulcer can be maintained in a population without any carry-over of cases from one season to the next. As the causal bacillus is difficult to culture and is easily destroyed, it is unlikely that infected fomites or dust carry the infection, and there is no evidence that it is harboured by animals. The human mouth is probably not an important agent in carrying the infection, and is certainly not an important factor in its dissemination.

(4) Infection is confined almost entirely to adults and older children, but the type of work being done is not of primary importance. The disease is one of rural or semi-rural living conditions, but needs a reasonable density of population for its spread.

(5) Although some degree of trauma probably always precedes the appearance of an ulcer, this may be very slight.

(6) In an area where tropical ulcers are prevalent, certain sub-areas are much more heavily infected than others.

(7) There is no definite evidence that tropical ulcer is a deficiency disease, and neither malaria nor alcoholism appears to play any important part in its causation.

(8) The majority of tropical ulcers appear on a limited area of the body, but it is very doubtful whether the explanation advanced that this area is one of deficient blood supply is correct.

(9) The seasonal character of the disease and its predilection for one particular class and for certain geographical areas suggest that the infection is carried and harboured by an insect vector. The limited portion of the body normally affected suggests that this vector is a crawling insect.

III For many years in Assam it has been the opinion of medical men, especially those working on tea estates, that tropical ulcer is an insect-borne disease. This has been more a matter of conjecture than the result of a close study of epidemiology, the most widely held view being that abrasions are infected by various flies which have previously settled on existing ulcers and act merely as mechanical transmitters. The eye-fly (*Siphunculina sinicola*) has been incriminated, mainly owing to its close seasonal incidence with the disease. In only one case did a medical man succeed in infecting himself by allowing one of these insects to feed on a typical ulcer and then transferring it to an abrasion on his own body. Subsequent observers were uniformly unsuccessful, and moreover the disease is frequent in districts where the fly is unknown.

The average estate labourer's house is full of such insects as the cockroach, bed bug, louse flea sandfly, and housefly. These are more likely to attack children than adults but it is known that the former are rarely affected. Adults usually defaecate in some patch of scrub jungle not far from their houses, passing through moderately long grass on the way. Children under the age of 6 usually defaecate in the close vicinity of their houses on bare earth, and the older ones up to 12 on the roads adjacent to the coolie lines. There is thus a marked correlation between the sanitary habits of the various age groups and the incidence of the disease.

Outdoor winged insects bite any part of the body indiscriminately and, other things being equal if these were incriminated it would be expected that tropical ulcer would appear anywhere on the body, but in fact over 95 per cent of cases are confined to the leg, ankle, and dorsum of the foot.

The argument is put forward that the vector is a crawling insect which lives mostly in jungle or coarse vegetation and can retain an infection from one year to another. Ticks and mites are the insects which best fulfil these requirements, and are probably found in all countries where tropical ulcer is known. It has been established that they are capable of retaining certain infections from year to year. If the hypothesis is accepted that a tick or mite is the vector, the

(9) The seasonal character of the disease and its predilection for one particular class and for certain geographical areas suggest that the infection is carried and harboured by an insect vector. The limited portion of the body normally affected suggests that this vector is a crawling insect.

III For many years in Assam it has been the opinion of medical men, especially those working on tea estates that tropical ulcer is an insect-borne disease. This has been more a matter of conjecture than the result of a close study of epidemiology. The most widely held view being that abrasions are infected by various flies which have previously settled on existing ulcers and act merely as mechanical transmitters. The eye-fly (*Siphunculina funicola*) has been incriminated, mainly owing to its close seasonal incidence with the disease. In only one case did a medical man succeed in infecting himself by allowing one of these insects to feed on a typical ulcer and then transferring it to an abrasion on his own body. Subsequent observers were uniformly unsuccessful and moreover the disease is frequent in districts where the fly is unknown.

The average estate labourer's house is full of such insects as the cockroach, bed bug, louse, flea, sandfly, and housefly. These are more likely to attack children than adults but it is known that the former are rarely affected. Adults usually defaecate in some patch of scrub jungle not far from their houses, passing through moderately long grass on the way. Children under the age of 6 usually defaecate in the close vicinity of their houses on bare earth, and the older ones up to 12 on the roads adjacent to the coolie lines. There is thus a marked correlation between the sanitary habits of the various age groups and the incidence of the disease.

Outdoor winged insects bite any part of the body indiscriminately and other things being equal if these were incriminated it would be expected that tropical ulcer would appear anywhere on the body, but in fact over 95 per cent. of cases are confined to the leg, ankle and dorsum of the foot.

The argument is put forward that the vector is a crawling insect which lives mostly in jungle or coarse vegetation and can retain an infection from one year to another. Ticks and mites are the insects which best fulfil these requirements, and are probably found in all countries where tropical ulcer is known. It has been established that they are capable of retaining certain infections from year to year. If the hypothesis is accepted that a tick or mite is the vector, the

almost universal finding of ulcers below the knee is capable of a simple mechanical explanation namely as a man walks through long grass or brush most of the insects attaching themselves to the foot are brushed off but any above the ankle tend to remain there. Further the leucocytic infiltration into the base of the ulcer consists largely of eosinophiles, and this has been found to be very characteristic of lesions caused by the bites of hard est mites and various species of ticks. Again ulcers are most frequent among the strongest labourers, these being the people who go most into the jungle to cut firewood and hunt game.

IV The results of various methods of treatment and the literature on the subject are reviewed very fully.

The author describes the treatment of 483 cases, all being of the typical acute type. In 184 instances more than one ulcer was present, the number varying from two to eleven, while in this series both legs were affected in about one-third of cases.

Eight different methods of treatment were tried and are described in detail. The criterion of cure was firm and complete healing, in 47 days and the following routine treatment was found to be most satisfactory. After preliminary cleansing with sterile normal saline the ulcer is dressed twice daily for five days with sterile gauze moistened with a solution of 500 units of penicillin per ml. On the first day of treatment 100,000 units of penicillin are given intramuscularly in five three-hourly injections. From the sixth day onward, the ulcer is dressed daily with scarlet-red ointment but at the slightest sign of the sore becoming foul again the local penicillin dressing is repeated for three or four days. If serious reinfection has occurred it is advisable to repeat the parenteral administration of penicillin but each case should be treated on its merits. No difference was apparent in giving more than 100,000 units in any one course and the value of this drug is particularly apparent in ulcers over 1 inch in diameter. In the case of the larger ulcers skin grafting helps to reduce the time required for epithelialization.

One difficulty of penicillin treatment is that some form of refrigerator is necessary unless very large numbers of patients are being dealt with, when the whole contents of one phial can be used immediately it has been dissolved, as otherwise there will be much wastage. In the absence of penicillin the smaller ulcers can best be treated with the copper sulphate phenol and glycerin paste method, followed by a choice of cod liver oil, acridine emulsion or scarlet-red ointment (thus *Bulletin* 1808, v 35 808). The author apparently does not use surgical debridement. Of 128 cases treated by penicillin, 79.7 per cent. were regarded as successes with single ulcers of 1 inch or more in diameter 84.2% successful. 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

In each case a thumb-nail sketch is given of the disease as a whole and this is followed by a review of references to "neuropsychiatric manifestations and complications" that have appeared in the literature. The subject, however, is treated mainly from the point of view of the organic neurologist and, for example, the well-known neuropsychiatric manifestations associated with filariasis (Bancroft's) are not discussed.

Naturally, the sections vary in length: there are for example 54 references in the malaria section, most of which are of recent date, whereas the author has only been able to muster 4 for Bancroft's filariasis and they are all 20 or more years old; three of these refer to the finding of microfilaria in the blood vessels of the brain, and only one, an unimportant one, suggests that there are any associated symptoms.

The paper is a very laborious piece of work

PROTOZOOLOGY GENERAL

WARREN, J & RUSS, Sudie B. **Cultivation of Toxoplasma in Embryonated Egg An Antigen derived from Chorioallantoic Membrane** *Proc Soc Exper Biol & Med* 1948, Jan, v 67, No 1, 85-9, 1 fig

By means of toxoplasma-infected chorio-allantoic membranes from infected chicken eggs complement-fixing antigen was prepared. The membranes were ground in a mortar with alundum and a 10 per cent suspension was prepared in physiological saline buffered at pH 7.4. The crude suspension was frozen and thawed three times and clarified by 15 minutes' centrifugation at 3,500 r.p.m. The supernatant fluid, after the addition of merthiolate to 1:10,000, constituted the antigen. This was generally stored at -20°C . An antigen for use as control material was prepared in the same way from normal 16-day-old chick embryos. Sera were obtained from rhesus monkeys and guinea-pigs convalescing from a toxoplasma infection and from a number of patients suspected of suffering from toxoplasma infection. The fixation tests were performed as follows:—In tubes were placed 0.25 cc of the dilution of serum, 0.25 cc of the antigen and 0.5 cc of fresh diluted guinea-pig serum containing two units of complement. They were incubated at 5°C overnight. The haemolytic system, consisting of 0.5 cc of a mixture of equal parts of 3 per cent suspension of washed sheep erythrocytes in saline and diluted amboceptor (2 units) was added to the tubes. They were incubated at 37°C for half an hour and read in the usual manner. The immune animal sera were positive (1 in 200 to 400) as also were human sera from both proven and suspected cases of toxoplasmosis (1 in 16 to 128).

MACFARLANE, J O & RUCHMAN, I. **Cultivation of Toxoplasma in the developing Chick Embryo** *Proc Soc Exper Biol & Med* 1948, Jan, v 67, No 1, 1-4, 2 figs

Inoculation of toxoplasma—the "R.H." strain of SABIN—in the yolk sac of chicken eggs of 7 to 11 days' incubation resulted in the death of the chicken embryo on the 5th to the 6th day. Examination of the eggs showed numerous yellow-white plaques, 0.5-3 mm in diameter, on the chorio-allantoic and amniotic membranes. The areas surrounding the lesions were thickened and histologically represented regions of dense cellular infiltration containing numerous toxoplasma. Smears of the membranes revealed numerous toxoplasma, which were also present in the organs of the embryo. Inoculation of the parasites into mice, rats, chicks, rabbits and rhesus monkeys

produced infections which did not vary from those produced by inoculation of the original strain from the mouse. The passage through the chick embryo did not modify the parasite in any way. Attempts to cultivate the toxoplasma in the pooled embryonic fluid from 17-day fertile eggs were unsuccessful. Storage of infected membranes at 4 C. yielded viable organisms up to one month. Photographs illustrate the appearance of the normal and infected chorio-allantoic membrane and the difference between microscopic sections of these.

WINKER J VERLINDE J D VAN TRIEL, P H DAVEL, J & VAN DER ELST P
Isolation of Toxoplasma from Cerebrospinal Fluid of a Living Infant in Holland. *Proc Soc Exp Biol & Med* 1948 Mar v 67 No. 3 28-31

The diagnosis of toxoplasmosis is frequently made on the evidence of serological reactions and the presence of ocular changes in the patient. Final confirmation by demonstration of the organisms is much less frequent and seldom achieved, as it was in the case under review during life.

The patient, a child six weeks old on admission to hospital, appeared healthy during the first few weeks of life. When first seen in hospital he presented marked ocular changes, displacement and enlargement of the lateral ventricles and developing hydrocephalus.

The centrifuged deposit of the cerebrospinal fluid, when examined microscopically, showed numerous toxoplasma bodies. The cerebrospinal fluid, inoculated intracerebrally into mice, produced infections in the latter.

The serum of the child's mother showed strong neutralizing power against the organism when examined by Sabin's rabbit skin test. Cross immunity tests for neutralizing activity between the organism isolated and another human strain from America showed that the two strains were very closely related, if not identical.

ENTOMOLOGY AND INSECTICIDES GENERAL

CALLOT J La réaction de l'homme aux piqûres de moustiques. [Man's Reaction to Mosquito Bites.] In *L'air et l'homme et l'Europe* 1947 v. 22, Nos. 3-4 233-4

The author refers to the notes on this subject by MALLANBY (ibid. *Bulletin* 1947 v. 44 40 and 364) by BRISTOWE and by RIBBANS (ibid. 364) and in general confirms their conclusions on relative attractiveness of different persons to mosquitoes.

In his experience with *A. des aegypti* however, a person who is re-bitten continuously by the mosquito after an interval of several months presents a delayed reaction (Mallanby Stage I) after another interruption of 40 days followed by a new series of bites he passes directly into Stage III and thus state persists for three months despite daily bites.

On the other hand, experiment with *Culex* at the Roubaud show that the reaction produced in this case after the initial bite was that of stage II without Stage I having been entered at all.

The author has not succeeded in obtaining stage IV experimentally. He suggests that some people attain it, while others are free from any reaction from the outset. He draws a distinction between those who have never been bitten by mosquitoes and those who do not react to the bite and gives an example of a subject who had never been in contact with *A. des aegypti* but suffered no reaction whatever when he was bitten experimentally by this species.

STAGE H H A Vespid preying on Anophelines *Mosquito News* 1948, June, v 8 No 2, 73

FAY, R W, COLE, E L & SIMMONS, S W Toxicity of DDT Residues Effect of Surface and Surface Treatment on the Residual Toxicity of DDT against Adult *Anopheles quadrimaculatus* Mosquitoes *Soap* New York 1948, June v 24, No 6, 130-33, 157-9, 189, 3 figs

These experiments constitute an extension of earlier work and the same technique was employed [see CLAPP, FAY and SIMMONS, this *Bulletin*, 1947, v 44, 563, SIMMONS *et al*, *ibid*, 1946, v 43, 789, FAY, SIMMONS and CLAPP, *ibid*, 1947, v 44, 562] In brief, adults of *Anopheles quadrimaculatus* were exposed for sixty minutes in a small box, the sides of which are made up of various materials (in different tests) and treated with DDT at the rate of 200 mgm per sq ft The surfaces investigated were, plain pine plywood (standard), dry bamboo, rusty metal screen, rusty sheet metal, bark, new sheet metal, glass, tile, palmetto thatch, new metal screen, "plexiglass", shellacked wood, synthetic fabric, cement and waxed wood DDT was sprayed on as a xylene-Triton X emulsion, as a kerosene solution or as an aqueous suspension The results indicated a better persistent toxicity (up to forty-five weeks) on relatively rough surfaces (rusty metals, bark) "which might be expected to aid

spray coverage and adherence." Smooth but impermeable surfaces were next in order of efficiency, and least satisfactory were either waxed or shellacked surfaces (which might have softened and absorbed DDT) or else very porous materials (cement).

These results were true, generally speaking, of treatments with emulsion and kerosene solution. The suspension of the DDT wettable powder was definitely better on the absorbent cement and somewhat better on the new metal and glass; it gave inferior results on the rough surfaces of rusty metal and bark.

Various household cleansing measures were tested for their effects in reducing residual toxicity of DDT films. With fabrics, dry cleaning was most drastic, followed by vigorous brushing and (least serious) vacuum cleaning. DDT was removed from walls by periodic dusting, and more rapidly if a past cleaner was employed.

RAFFAELLI D. Determinazione colorimetrica del DDT sullintonaco delle pareti trattate. (Colorimetric Estimation of DDT on Treated Walls.) *Riv. di Parassit.* Rome, 1948, June 1, 9 No. 1, 79-83. English summary (2 lines)

The following method, derived from Chalkin's reaction (*Ind. Eng. Chem., Analytical Ed.* 1948 v. 18, 279) is useful for rapid estimation of DDT present on walls and other surfaces sprayed for residual insecticidal effect.

The superficial layer of surface is scraped from 100 sq. cm. on to a piece of paper and thence transferred to a test tube. The DDT is extracted with about 4-5 ml. of ether which is decanted into another tube. This tube is placed on a water bath and the extract is evaporated to dryness. To the residue 2 ml. 1 glacial acetic acid are added and the tube is warmed for a short time on the bath with agitation, then 10 ml. of sulphuric acid (D 1-84) are added and the mixture is heated on the bath for ten minutes.

The presence of DDT is indicated by a yellowish colour with a tinge of green, the depth of colour indicating the amount of DDT present. For quantitative work standards are made up with 0.5 to 5 milligrammes of DDT. The colours produced in this reaction are then matched by dilutions of a solution of Grubler meta chrome yellow - R.D. to which a trace 1 Grubler methyl gr. (n) has been added. These solutions are kept as reference standards.

This method is accurate if the DDT application has been made with kerosene solution. When an emulsion or dispersion has been employed, there may be traces of emulsifying or dispersing agents which introduce a brownish tinge, sufficient to interfere with a quantitative determination. This can be avoided as follows. The deposit from the ether extract is treated with a few ml. of concentrated potassium permanganate and placed on the water bath to evaporate to dryness. A new ether extraction is then made and the test conducted in the usual way.

SCOTT J. A. An Apparatus for removing Tropical Rat Mites from Large Quantities of Bedding Materials. *J. Parasitology* 1948 34 31 31-2, 132-3 1 l. n.

This apparatus was constructed for the purpose of extracting with a single working day large numbers of adult and nymphal tropical rat mites (*Liponyssus bacchi*) from about 4,000 cc. of wood shavings and an equal charge of hay. It consists of an open trough of galvanized sheet iron (2 ft 8 in. x 8 in. x 4 in. deep) surrounded by moist containing water maintained at a depth of 1 in. An infra-red bulb of 50 watts is suspended over the trough moves along at the rate of 1 in. per hour. The mites are driven ahead of the wave of heat and are

collected by means of a suction bottle. The bottom of the trough is lined with asbestos cement to delay heat conduction and prevent mites being killed when they drop off the ends of pieces of hay. A line drawing illustrates the apparatus and gives all necessary dimensions; it also shows a simple device for collecting mites which fall into the water in the moat. *H. S. Leeson*

REPORTS, SURVEYS AND MISCELLANEOUS PAPERS

SERGEANT Ed Le Professeur Félix Mesnil Zoologiste et Chef d'Ecole en Médecine coloniale [Professor Felix Mesnil, Zoologist and Chief of the Colonial School of Medicine] Reprinted from *Rev de la Méditerranée* 1948, v 5, 24 pp

DUBOIS, A & DUREN, A Soixante ans d'organisation médicale au Congo Belge [Sixty Years of Medical Organization in the Belgian Congo] *Liber Jubilæis J Rodham (Soc Belge Méd Trop, Brussels)* 1947, Dec, 1-36 [19 refs]

This contribution to the *Liber Jubilæis J Rodham* contains an account of the development of the medical services of the Belgian Congo, with which, from 1903 to 1925, Rodham was so closely associated, he was the head of that service for five years. The service has grown from small beginnings, and as a result of special needs it has developed in various directions. For instance, the heavy incidence of sleeping sickness led to the development of a special section, which in turn has been expanded into the *Service d'Assistance Médicale Indigène* and finally into the Foréamu service.

Training in medicine is given on a large scale to African auxiliaries and to the various subordinate grades, and schools for these purposes exist in nine cities. The government assumes responsibility for the health of the community, but encourages private initiative, for instance the Red Cross and university foundations, religious missions and the medical services of the big industries. In 1944 there were 176 physicians in government and Foréamu service, 127 in other organizations, 15 private practitioners, and large numbers of *infirmières* and *agents sanitaires* [whose status is not here defined].

Scientific research in the Congo has a distinguished history, and there are now laboratories at 5 government stations and at various mines and Red Cross institutions. Scientific missions have played a great part in medical development, and continue to do so.

Of the important diseases, malaria is mentioned first. For trypanosomiasis the index of infection has fallen from 1.1 in 1927-29 to 0.23 in 1946 (3½ million examined in 1946). Schistosomiasis (mostly intestinal) is fairly common in the south and east, where *Planorbis adowensis* and *P salinarum* are the snails. Vesical schistosomiasis does exist, however, and *Physopsis africana* is the host. The dysenteries, relapsing fever, leprosy (58,830 cases known), venereal diseases, cerebrospinal fever, yaws (quarter of a million treated each month, permanently affecting 2-3 per cent of the population), tuberculosis, plague, yellow fever, smallpox and murine typhus, are all important. Some of them are rather potential than actual sources of widespread danger, but all need, and receive, considerable attention.

The article is an interesting conspectus of the present situation.

Charles Wilcocks

Sironi, M. *Relazione Triennale (1945-1947) sull'attività del Laboratorio*. [The Work of the (Entrea) Laboratory for the Period 1945-47] *Bull. Soc. Ital. di Med. e Ig. Trop.* (Sec. Entrea) 1948, v. 8 No. 12, 31-53. [19 refs.]

The Laboratory of Hygiene and Prophylaxis of Entrea has become also the Central Laboratory of Pathology and, with a staff comprising a director an assistant 6 technicians, an administrator a registrar and 4 laboratory boys (*aiuti di servizio*) it deals with 100-120 specimens a day. For purposes of this report the work has been divided into five sections:

(1) *Biochemical* dealing with 27,180 specimens during the period, including examinations of urine, gastric contents, cerebrospinal fluids, blood samples and suchlike not easily separated from

(2) *General microscopic and parasitological* Search for intestinal protozoal and helminthic infestations, differential blood counts and blood parasitism malaria plasmodia and spirochaeta.

(3) *Serological* including 36,520 Wassermann reactions 5,056 W. R. Flex tests and preparation of antisera for precipitin reactions blood grouping, etc. In an outbreak of typhus in Asmara in 1946-47 *Proteus OX19 OX₁₉* and *OXK* were used. Reactions to the first named were much the most numerous. Of 100 "nationals" [presumably Italians] 44 so reacted in a dilution of 1:1280 5 to *Proteus OX₁₉* while of 1,000 indigens the respective figures were 32.3 and 8.1 per cent.

(4) *Histological* and (5) *Bacteriological*.

An anti-rabies dispensary has been joined to the laboratory where the vaccine is prepared and treatment given. The author states that undulant fever due to *Br. melitensis* and *paratuberculosis* is a disease of the towns. *Br. abortus* infection, he avers, does not occur. Bacillary dysentery is apparently uncommon during the three years 350 samples of faeces have been cultivated and the *Shigella* Kruse organism has been isolated on 8 occasions, a Flexner organism 4 times and a Saigon strain once. Amoebic dysentery is more common, but not above 15-20 per cent. [the number examined is not however stated] and has become more widespread during and after the war years.

SOUTH PACIFIC BOARD OF HEALTH. *Minutes of the Meeting held at Suva, Fiji, on the 25th, 28th and 31st October 1946* [BUCHANAN J. C. R. Chairman] 6 pp. Fiji Govt. Press.

At the inaugural meeting of the South Pacific Board of Health many subjects relating to that area were discussed. The Chairman Dr J. C. R. Buchanan, who holds the dual office of Inspector General South Pacific Health Service and Director of Medical Services Fiji, outlined the problems connected with health administration in the different islands and made it clear that the need was for information which would include a domestic interchange of pathological information.

The meeting discussed questions relating to establishment research diet and nutrition, epidemiology and training of staff. It is evident that the Board were fully alive to the nature of the problem facing them and to the need to take whatever steps to deal with them that might be available in cooperation with neighbouring territories, large and small.

The establishment expenditure of the Service Headquarters and the estimates for 1945-46 are shown as appendices to the minutes.

H. J. O'D. Burke-Smith

South Celebes, the large island to the east of Java, has a homogeneous population of Malays, 4 million inhabitants, with a density varying from 2 to 200 per square kilometre. They are agriculturalists. Its capital, Makassar, headquarters of the public health service, has a population of 180,000, with one physician for 7,000 inhabitants.

An interesting account is here given of the principal diseases of the territory. One might have expected a reference to the Celebes vibrio, an even stronger competitor because of its cholera, not dysentery, syndrome, for equality status with the so-called "true" cholera vibrio than the El Tor variety. Cholera is not mentioned among the diseases of the island. Malaria is the most important sickness, with a heavy mortality toll among infants and young children. In some districts 50 to 90 per cent of the school children have large spleens, while some 300,000 out of 850,000 inhabitants of endemic areas suffer from chronic malaria. Malaria is, however, of small importance in the town of Makassar. Yaws is once again receiving the attention of the physician. Each patient should receive 3 salvarsan injections and every physician gives monthly some 1,000 injections, in some cases up to 4,000. There is serious shortage of salvarsan. Other diseases mentioned are avitaminoses such as beriberi, hookworm, endemic goitre, leprosy, tuberculosis, rabies and mental diseases. Filariasis and trachoma are not much in evidence.

Mortality and birth statistics are not yet forthcoming. Venereal diseases are not troublesome in rural areas, but are increasing in Makassar.

BRITISH GUIANA, MOSQUITO CONTROL SERVICE MEDICAL DEPARTMENT
 Annual Report for the Year ended 31st December 1947 [EDDEY, L G,
 Deputy Director of Medical Services & Acting Chief Officer] 7 mimeo-
 graphed pp

The Yellow Fever Service and the Malaria Research Service in British Guiana have now been amalgamated into the Mosquito Control Service, but the two sections for *Aedes* control and for DDT spray, are kept separate. The former comprises 82 and the latter 78 persons, and the office a staff of 4.

No *Aedes* were found during the year's searches, in Georgetown, Demerara River Estuary, Bartica etc., Mackenzie-Wismar, New Amsterdam, Berbice, or in trains. In these areas routine measures are taken against breeding, and 5 per cent DDT in kerosene is extensively used as a spray at an estimated dosage of 150 mgm DDT per square foot. All trains were re-sprayed during July and August.

Precautions against introduction of insects by air are taken by the authorities of the U.S. Air Base, and local British Guiana Airways aircraft are disinfested by the company. Inter-colonial schooners and government ships are sprayed with DDT from time to time with good results, and large ocean-going vessels, which are treated with DDT, are no longer sources of reinfestation.

Yellow fever immunity surveys were continued. 220 sera being examined at the Rockefeller Foundation Laboratory, Bogota Colombia, of these 34.1 per cent were positive for protective bodies. The specimens were mostly taken from people in the interior, and positive results were obtained in children; these findings indicate that jungle yellow fever still occurs to a considerable extent in the Aboriginal Indians.

SPONZA M. Relazione Triennale (1945-1947) sull'attività del Laboratorio. [The Work of the (Eritrea) Laboratory for the Period 1945-47] *Bol. Soc. Ital. di Med. e Ig. Trop. (Sez. Eritrea)* 1948, v. 8, No. 12, 31-53 [19 refs.]

The Laboratory of Hygiene and Prophylaxis of Eritrea has become also the Central Laboratory of Pathology and, with a staff comprising a director an assistant 8 technicians an administrator a registrar and 4 laboratory boys (*uomini di servizio*) it deals with 100-120 specimens a day. For purposes of this report the work has been divided into five sections:

(1) *Biochemical* dealing with 27-180 specimens during the period, including examinations of urines, gastric contents, cerebrospinal fluids, blood samples and suchlike not easily separated from.

(2) *General microscopical and parasitological*. Search for intestinal protozoal and helminthic infestations, differential blood counts and blood parasites: malaria, plasmodia and sporochia.

(3) *Serological* including 38,520 Wassermann reactions, 8,054 Weil-Felix tests and preparation of antisera for precipitation reactions, blood grouping, etc. In an outbreak of typhus in Asmara in 1946-47 *Proteus O119 O1*, and *OXA* were used. Reactions to the first named were much the most numerous. Of 100 "nationals" (presumably Italians) 44 so reacted in a dilution of 1:1280-5 to *Proteus O1*, while of 1,000 indigenes the respective figures were 32.3 and 8.1 per cent.

(4) *Histological* and (5) *Bacteriological*.

An anti-rabies dispensary has been joined to the Laboratory where the vaccine is prepared and treatment given. The author states that nodulant fever due to *B. mediterraneus* and *paramediterraneus* is a disease of the towns. *B. abortus* infection, he says, does not occur. Bacillary dysentery is, apparently, uncommon during the three years 350 samples of faeces have been cultivated and the Shiga toxin organism has been isolated on 8 occasions, a Flexner organism 4 times and a Saigon strain once. Amoebic dysentery is more common, but not above 15-20 per cent. [the number examined is not by ever stated] and has become more widespread during and after the war years.

BRITISH GUIANA, MOSQUITO CONTROL SERVICE MEDICAL DEPARTMENT
 Annual Report for the Year ended 31st December 1947 [EDDEY, L G,
 Deputy Director of Medical Services & Acting Chief Officer, 7 mimeo
 graphed pp]

The Yellow Fever Service and the Malaria Research Service in British Guiana have now been amalgamated into the Mosquito Control Service. But the two sections for *Aedes* control and for DDT spray, are kept separate. The former comprises 82 and the latter 78 persons, and the other section of 4.

No *Aedes* were found, during the year's searches, in Georgetown, Demerara River Estuary, Bartica etc., Mackenzie-Wismar, New Amsterdam, and the trains. In these areas routine measures are taken against house flies. 150 mgm DDT per square foot is extensively used as a general measure of control.

Precautions against introduction of insects by air are maintained at the U.S. Air Base, and local British Guiana aircraft are disinfected by the company. Inter-colonial schooners and a small motor launch are sprayed with DDT from time to time, with good results. The launch is sprayed which are treated with DDT. We no longer have any mosquitoes.

Yellow fever immunity tests were conducted in the summer of 1947. The Rockefeller Foundation tests were conducted in the summer of 1947. 100 per cent were positive. In the summer of 1947, 100 per cent were positive. These findings indicate that the immunity is of a high level and of a long extent in the population.

No viscerotomy specimens were received during the year and no cases are reported from hospitals. Vaccination is carried out as required in Georgetown. Total general expenditure was 182,792 B.W. I. dollars. Charles Wilcocks

IXONS E. E. Report of the Medical Mission to Puerto Rico and to the Virgin Islands. *J Amer Med. Ass.* 1948 Apr 10 v 138, No. 13 979-84.

The author was a member of a medical mission of 8 eminent medical men and one woman (Director of a school of nursing in Chicago) who were invited by the U.S. Secretary of the Interior to report on medical conditions in Puerto Rico and the Virgin Islands early in 1948. He reports his general impressions in this article which has considerable interest for medical administrators of tropical countries.

The greatest single factor in the health of the people of Puerto Rico is that of nutrition—the total food supply locally produced and imported, is not enough for the population of over 2,000,000 which is increasing by 65,000 each year. Some improvement may come from development in the use of fruits like mangoes and guavas, at present little used, and of fish, but that improvement cannot be great. It has been suggested that emigration would keep the population within reasonable limits, but this would need to involve over 50,000 each year. Increase in industrialization on present lines cannot cope with more than part of the problem. The net reproduction index of Puerto Rico is 1.7 the highest in the world, and the 77 birth control clinics have so far had no demonstrable influence on the birth rate.

There are about 800 physicians, 200 of whom live in or round the capital San Juan. The country districts are poorly supplied. Many of the doctors of municipal and district hospitals receive 300 to 450 dollars a month, and some give good service in return, but according to the author many more give poor service. There are 65 type A rural health units and 21 type B or purely public health units. These serve the country districts but they are not described—the service at some is said to be very poor.

There are 5 district hospitals and 7 others are planned—most of these are good and have recently improved under the guidance of Dr. J. A. Pons, the commissioner of health. There are municipal hospitals in several towns, some good, some not. Apparently the difficulty is largely due to the political domination of hospital operation and the employment of physicians who have poor ideals or no ideals at all. It would be wise to transfer these hospitals to the central government. Two hospitals for tuberculosis (and another projected) one for the insane and one leprosy colony are also functioning, and there are several large private hospitals and clinics, which do excellent work.

For medical education students go to the United States and 160 are now there. If this process can be continued, the demand for doctors will eventually be met. In addition there is the group of practicantees many of whom have been male nurses but who have expanded their activities and peak off themselves as minor surgeons. Their status was made legal in 1945 but many of their performances are regarded as injurious to the persons on whom they work. For post-graduate medical study the School of Tropical Medicine (which is conducted jointly by the government the University of Puerto Rico and the Columbia University) is in the author's opinion the greatest single factor in improving educational standards in medicine. It offers training in public health and it operates a dispensary with 20,000 patients a day.

In the Virgin Islands the total population is about 30,000. Agricultural possibilities are slight and the economic future may depend on tourism. Government care has been the rule for many years in the provision of free

financial aspect of the project, the legal aspect of antimalarial operations and the maintenance of drained swamps. There are appendices reproducing the various forms used in the operation of the scheme, as also a summary of standing orders for maintenance workers and the provisions of a government ordinance relating to mosquito destruction. There are also a number of excellent photographs, maps and diagrams, among which a series of sketches by Mrs Gilroy deserves special mention.

The text is written with clarity and vigour, and contains a wealth of information relating to the essential requirements on which depend the success or failure of an antimalarial drainage scheme. Every sentence contains matter of practical importance to the field worker. The title suggests that the subject matter is limited to coastal swamp drainage, but the book will be of service to those engaged in antimalarial drainage in any type of terrain, for the basic principles on which the success of all such schemes depends are essentially similar. Moreover, though written primarily for health officers, it will be helpful also to others connected with antimalarial schemes, administrators and field workers alike. Health authorities in malarious countries will be well advised to order copies of this book for distribution to all members of their staff who are likely to be called upon to plan or supervise antimalaria drainage works. It might with advantage be circulated also to hydraulic engineers operating in such regions, who do not always appreciate the essential differences between swamp drainage as a purely engineering problem and as an *Anopheles* eradication measure.

SANDOSHAM, A. A. *Malaria in Malai. A Handbook for Anti-Malaria Students*. With a Foreword by T SATO. pp xv+288, 22 figs & 8 pls (5 coloured). [Bibliography.] Reprinted with corrections 1945. Syonan [Singapore], Syonan Tokubetu-Si.

No claims to originality are made for the subject matter contained in this book. It is a compilation from many sources, put together in the form of lecture notes and then expanded into an elementary text book to suit the course of studies in malariology organized by the Health Department in Malaya.

The author divides his subject into seven sections. The first is mainly historical but also contains general remarks on blood parasites and stains, the second section [part of which will have to be rewritten since the discoveries of SHORTT and GARNHAM] introduces the beginner to the malaria parasites, questions of immunity, climate, endemicity and epidemicity in Malaya. The anopheline mosquitoes of the country are dealt with in the third section. The fourth section is devoted to a good practical description of malaria and anopheline survey methods and the making of survey maps and reports. Section five deals with control and describes the usual well-tried ways of draining, oiling and so on, followed by notes on treatment and drug prophylaxis. Again, parts of this section need to be brought up to date. For example, the formulae for Dover's cream and Bamber oil are given but dimethyl phthalate is not mentioned. The various formulations of DDT are omitted, and there is no reference to paludrine. A useful brief section on culicine mosquitoes comes next and the seventh section contains appendices on instructions in microscopy and the preparation of thin and thick blood films and staining. Aids to the identification of malaria parasites describe side by side the appearances of the different species in thin and thick film preparations, and aids to the identification of seventeen out of some forty species of Malayan anopheline species include illustrated descriptions of the main distinguishing characters.

There is a full index, but no attempt has been made to give a full list of references to works which have been consulted or from which data have been

zones in this region, the first of which is completely submerged by the diurnal neap tides, the second for a few days monthly by the spring tides and the third only twice each year by the high equinoctial springs. The second zone in which occur extensive groves of the white mangrove *Avicennia nitida* is characterized by large-scale breeding of *A. melas*, whilst the first and third are comparatively innocuous. Control of breeding by means of larvicides had proved ineffective and recourse was therefore had to swamp drainage on an extensive scale.

The scheme was initiated in 1942 for the control of malaria among service and particularly among R.A.F. personnel. It was continued after 1944 as a Government undertaking, financed from Colonial Development and Welfare funds. In all, more than six square miles of swamps lying within the urban district of Lagos have been successfully drained.

By a fortunate chance the R.A.F. personnel detailed for the project at the commencement of operations included a Norfolk hedger and ditcher, a borough council navvy and a landscape gardener's mate—all men accustomed to digging and hard manual labour in general. To each of these was assigned a squad of 10 Africans for training and thus a nucleus of skilled diggers was created round which the main body of the labour force was subsequently built up. There can be no doubt that the success of the scheme was largely due to the high quality of the supervisory staff and to the sustained enthusiasm which Dr Gibson was able to maintain among all those engaged in the operations.

Since no satisfactory attempt at drain excavation can be made in a swamp subject to flooding until the tides are excluded, the first stage in swamp drainage is the construction of a protective bund. Contour drains are dug following the margin between the swamp and the higher land behind it, and these are connected to the main drains so as to conduct the water collecting in them by the shortest route as possible to the lagoon. Subsidiary drains are constructed where these are found essential but as in every good drainage scheme all drains are restricted to the absolute minimum necessary for the effective drying of the land.

Sluices, constructed with the aid of coffer dams, are placed in the bund at the outfall of each main drain. These are operated by hand, the possibility of using automatic sluices having been ruled out because of the very small head of water in which breeding of anopheline mosquitoes is very rare in well-maintained drains as also in the numerous shallow drains in the bunds. Fortunately these latter have not proved a serious cause of damage to the banks.

The organization of swamp drainage in the Lagos area is based on the task system, which is preferred on the grounds that it entails a minimum of supervision, needs less attention to punctuality, allows of accurate estimation of quantities of work and is popular with the labourers who know that the better they work the sooner they will be allowed to go home. Special attention is given to the training of foremen and the necessity for effective backing up in the execution of their duties on the part of the European staff is emphatically stressed.

The financial aspect of the project is treated in detail, the method of costing, daily costs being of especial interest. If the system adopted is to balance is truck from day to day between available funds and amount expended. This relation, viewed in the light of work progress, indicates whether or not the two are keeping pace. The cost of maintenance when the scheme is complete and continued eradication of anopheline breeding, averages about 15 per cent of the original outlay. A progressive decrease in annual expenditure is expected after the consolidation of the earth work is complete.

The book comprises two main sections, the first giving a detailed account of the practice of swamp drainage, the second describing in comprehensive terms the organization of a swamp drainage scheme. Other sections deal with the

financial aspect of the project, the legal aspect of antimalarial operations and the maintenance of drained swamps. There are appendices reproducing the various forms used in the operation of the scheme, as also a summary of standing orders for maintenance workers and the provisions of a government ordinance relating to mosquito destruction. There are also a number of excellent photographs, maps and diagrams, among which a series of sketches by Mrs Gilroy deserves special mention.

The text is written with clarity and vigour, and contains a wealth of information relating to the essential requirements on which depend the success or failure of an antimalarial drainage scheme. Every sentence contains matter of practical importance to the field worker. The title suggests that the subject matter is limited to coastal swamp drainage, but the book will be of service to those engaged in antimalarial drainage in any type of terrain, for the basic principles on which the success of all such schemes depends are essentially similar. Moreover, though written primarily for health officers, it will be helpful also to others connected with antimalarial schemes, administrators and field workers alike. Health authorities in malarious countries will be well advised to order copies of this book for distribution to all members of their staff who are likely to be called upon to plan or supervise antimalaria drainage works. It might with advantage be circulated also to hydraulic engineers operating in such regions, who do not always appreciate the essential differences between swamp drainage as a purely engineering problem and as an *Anopheles* eradication measure.

ADOLPH, E. F. and Associates [Dept. of Physiology, University of Rochester]. *Physiology of Man in the Desert*. pp. xiii+357 184 figs. 1947 New York & London Interscience Publishers, Inc. {30s.}

During the war years much research on the responses of man to his thermal environment was sponsored by the United States Office of Scientific Research and Development and prominent among the scientists engaged on this work were the authors of this book. Adolph's work on water balance is well known, and in their wartime studies he and his colleagues were largely concerned with the water and heat metabolism of man in the desert.

The book is a cooperative effort of the members of the Rochester Desert Unit. It deals with body heat exchanges, sweat formation and water turnover in a general way and then turns to specific problems of life in the desert. Rates of sweating, urinary excretion, fluid intake water requirements and water shortage are discussed. Then come chapters dealing with various aspects of dehydration, on survival without drinking water in the desert, and on the water losses of men on life rafts. In a chapter comparing tropical with desert conditions there is a useful discussion of the physiological assessment of environmental stress. For comparing the stresses imposed by desert and tropical environments, the authors use as their index the rate at which the body gains heat from the environment.

The penultimate chapter by Adolph, includes a discussion of the factors which render and keep a man desertworthy. There is a final chapter of summary and conclusions, and the last few pages of this give practical conclusions of great value to those responsible for men in the desert.

This book is a highly important contribution to environmental physiology. It contains a wealth of information sometimes in tabular form sometimes in clear diagrams, and sometimes in the form of beautifully produced maps.

Although it appears as one of a series of monographs on the physiological sciences it will appeal to many who are not physiologists. It is clearly written and extremely interesting and it is well produced.

Thomas Bedford

PASSMORE, R. [M.A., D.M. Oxford, Captain, Indian Medical Service Nutrition Research Laboratories, Indian Research Fund Association, Coonour S. India]. *Nutritional Diseases in India described for Students and Practitioners*. pp. ii+128+1 15 figs on 13 pls & maps. 1948. Calcutta U.N. Dhur & Sons Ltd. {Rs. 10}

The book is written primarily for the medical student and practitioner in India. The author feels that hitherto these categories have fallen between two stools—the detailed book on nutrition written for the research worker and the popular book on nutrition written for the non-medical public.

The first chapter is appropriately on the causes of sickness and death in India and their relation to diet. The opening paragraph could not have been better chosen for it consists of Sir Alexander Russell's oft-quoted words on the overriding importance of the recognition of the dietary defects of the population of India whatever disease is being specifically considered from the preventive aspect. The author then proceeds to consider the causes of death in India and to point out the part played by defective nutrition in each case, he has usually backed his argument by statistics from the Public Health Commissioners' reports or from those of provincial directors of public health. The diseases discussed include malaria and "fever", dysentery and diarrhoea, respiratory diseases, and leprosy, infantile and maternal mortality are also included. Most of the arguments are well-known to the reviewer, but this will probably not be the case with the general reader who may not be quite so familiar with the subject and the author will certainly make his point. Somewhat surprisingly most of his statistical data are at least 10 years old.

The chapter ends on the note on which it began, the author points out that the nutrition problem can only be tackled by revolutionary changes in agriculture and in the social, political and religious life of the community, and that, although it is not the doctor's business to bring these about, it is his business to point out how necessary they are.

The second chapter is on malnutrition, and generally speaking it is a very satisfactory one. The author has described the stigmata of malnutrition without necessarily specifying which particular food deficiency is responsible for each defect. This is a healthy modern tendency in nutritional studies, it has been necessitated to some extent by the obviously mixed aetiology of most clinical manifestations of malnutrition, and by the many mistakes that have been made in the past through unjustifiable dogmatism. The chapter concludes with a discussion on treatment of malnutrition. Interpolated in the middle of this chapter, under a section headed "The Blood and Urine", are a few remarks in very small print on sprue and ariboflavinosis. The impression conveyed is that this was an afterthought, late in the production of the book when the author suddenly discovered that he had not mentioned these two words, neither of which as words he appears to like.

His paragraph on sprue opens and concludes thus —
 "Sprue is a condition very similar to the picture of malnutrition already described. nutritional diarrhoea is a sound descriptive diagnosis, preferable in most instances to 'sprue', a Dutch word apparently meaning an inflammation of the tongue." It is felt that the after-thought, if it was one, was unfortunate and that it would have been better to have ignored the disease, which as it is seen in the European does not, in the reviewer's opinion, play any part in the nutrition problem of the native of India.

In Chapter 3 is given a good description of certain specific deficiency diseases, beriberi, pellagra, scurvy and rickets and osteomalacia.
 The next chapter is on anaemia in relation to nutrition. It is not one of the better chapters of the book, the author does not seem very familiar with the subject and did not write a very orderly chapter, although he started appropriately with physiological considerations and a reference to Whipple's work on blood formation and diet. His short excursion into haematological methods was unfortunate, for no very good reason he chose to describe the method of calculation of the mean corpuscular values, MCV and MCHC, and got the first one wrong (possibly a misprint, but it is repeated).

The next two chapters are again sound ones, they are on "Diseases probably due to food poisons" and "Miscellaneous Diseases in which the Errors in Diet may be a Contributory Factor", respectively. However, the publishers evidently did not approve of the author's doubts and have called them

"Diseases due to Food Poisons" and "Diseases caused by Errors in Diet" on the page headings. The former include lathyrism and epulemic dropy and the latter tropical ulcer, goitre, peptic ulcer, diabetes, dental disease, carbuncles of the liver and urinary stone. The author, however, is unequivocal in his opinion that diet has little to do with stone formation.

The book concludes with a number of useful appendices, food analyses, diet tables, etc.

It is a book that will serve its purpose well. It is pleasing to handle and read and the price is moderate. The illustrations are mostly good and relevant but it would have been better if they could have been distributed into their appropriate places in the book instead of being concentrated at the beginning. Finally, it is singularly free from misprints. However, for the sentence "The normal stimulus of thirst appears to be in obeisance" the reviewer who has also published books in India, extends his sympathy to the author in the words of John Bradford, "But for the Grace of God there goes".

RABIES

PIRINGER, W Die Impfmethode gegen Lyssa nach Semple - [Anti-Rabies
Vaccination by Semple's Method] *Ztschr f Hyg u Infektionskr* 1944,
Nov 12, v 126, Nos 1/2, 7-35, 1 fig [26 refs]

During the period 15 5 1938-31 12 1942, when Semple's phenolized vaccine was used in Vienna for the treatment of bitten persons, there occurred but one case of rabies (23 days after infection) and one non-fatal case of post-vaccinal paralysis among the 1 735 persons treated

Close scrutiny of the records of treated persons, classified according to the condition of the biting animal, permitted transfer of a very large number from category C (those bitten by animals simply suspect) to a new category E (those in contact with but not bitten by, an animal which, although unknown, was yet most probably healthy) Patients in category E and in category D (where the biting animal proved healthy after observation or laboratory inoculation tests), having been at slight, if at any, risk, are not taken into account when the author calculates the incidence of rabies among the treated, but are included when he estimates the frequency of paralytic accidents His evaluation of anti-rabies treatment, being based solely on the results obtained in respect of persons actually at risk shows no favourable bias, therefore, *vis-à-vis* the method employed

Apart, however, from the evidence based on statistics improperly considered, favourable results of anti-rabies treatment in recent decades may be traceable to a diminished virulence of the street virus present in some particular region such as Austria a diminution probably effected by the occurrence of rabies in only one species

In the author's view, until reports from Institutes, dealing with the successes and failures of anti-rabies vaccination, contain wholly accurate and comprehensive data on the occurrence of rabies among animals living in freedom or captivity and on the character of the street virus within the radius of each Institute's sphere of activity, a comparison between statistical series cannot be attempted and the value of the different methods of vaccination cannot be assessed

SIEGLER, A M Encephalitis due to Antirabies Vaccine Report of a Case
US Nat Med Bull 1948, July-Aug, v 48, No 4, 620-25 [11 refs]

A case of an encephalitic reaction due to anti-rabies vaccine in a child with no history of allergy is described An 8-year-old Negro boy, bitten on the forearm by a stray dog, had had the wound cauterized immediately and on

following day, had begun a 14-day course of anti-rabies treatment with phenolized (Semple) vaccine. Two days after completion of treatment, the child developed a staggering gait and complained of headache, drowsiness and double vision in the right eye. In the course of the next two days prior to his admission to hospital, the child experienced generalized weakness and was observed to drool to masticate only with great difficulty and to have fine tremors in all the extremities when sitting or standing. His tongue deviated to the right and his speech was slurred and unintelligible. Dr. wastes and headache persisted. His temperature rose to 101.6°F but there were no chills, vomiting or convulsions and there was no incontinence.

Clinical examination on the patient's first day in hospital revealed *after admission* that in the fundus there was physiological cupping, but no choking or papilloedema. The tongue protruded towards the right and drooling was noted but associated pharyngeal and palatal movements were normal. No gross abnormal movements were observed. The abdominal and cremasteric reflexes were absent and the deep tendon reflexes all diminished, but the right triceps was more active than the left and the right biceps was more active than the left. Babinski's sign was definitely extensor on the right but equivocal on the left. Sensation was grossly intact and there were no cerebellar signs.

On the second hospital day a definite left central facial paralysis was noted and a paresis of the left upper eyelid.

By the seventh hospital day the extra-ocular muscles were normal, the facial paralysis had subsided and the patient had regained almost all of his muscle power. On the twelfth day the child was completely symptom-free and was discharged from hospital in excellent condition. In this case it is worthy of record that investigations at the Rockefeller Institute to exclude any known type of virus encephalitis were made on the cerebro-spinal fluid and blood and were reported as negative.

In his commentary on the frequency, aetiology and treatment of the paralytic accidents of anti-rabies treatment the author draws attention to the already sufficiently established facts (a) that children, who suffer so frequently from bites, are infinitely less liable to paralysis than adults (b) that the aetiological agent is undetermined and (c) that there is no specific treatment for the condition. G. Stuart

MALARIA

WEYER, F. Bemerkungen zur gegenwärtigen Malariafrage in Deutschland.
[On the Present Malaria Situation in Germany. Reprinted from *Fortschr.
Heilk.* 1948 Jan 30 Nos. 34-36: 9]

Malaria in the present-day Germany seems to be a really serious problem. The extension of the theatres of war to malarious countries, the introduction of prisoners of war and the return of their own soldiers to Germany have brought about a large increase of cases. Since 1941 there have been 377 cases in prisoners of war in Brandenburg Province, 73 in the troops, 53 in foreign workers and 11 in the civilian population. 9 of these have acquired the infection locally. In 194 there were 18 autochthonous cases, in 1943 8, in 1944 141, mostly in a small focus on the Tegeler See to the north west of Berlin. After the war ended conditions became much worse. Return of troops and prisoners, the stream of refugees back, proper supervision, cessation of all reasonable measures of hygiene or prophylaxis, the lowered constitutional strength of the people all played part. Thus an endemic focus (malaria) in East Prussia.

Malaria

Vol 45, No 12]

The author compares the present condition with that after the first world war. In 1918-19 at Emden malaria station there were 6,839 cases and malaria was introduced during the war from the Balkan front. Small epidemics occurred in Emden in 1926 (571 cases), in 1938 (327 cases), in 1939 (213 cases) and thereafter fewer each year, 56, 16, 17, 10, 10, and 6 in 1945. Since then cases have been reported from Hamburg, Schleswig-Holstein, Lower Saxony, the Rhineland, North Württemberg, Karlsruhe, Mecklenburg and Pomerania in the Russian zone of Berlin, up to July 1946, 662 cases were recorded, of which 220 acquired the infection in Berlin itself, thereafter cases increased rapidly in this zone, at the beginning of September more than 1,000 had been registered. In the same year over 200 cases were treated in Frankfurt-am-Oder and its environs, 3 relapses and 197 fresh cases, in Schleswig-Holstein 470 cases, 190 autochthonous, STEINIGER, who reported this, estimates that the actual cases probably numbered twice this. In a transit camp at Friedland in 1945-46 Thonnard-Neumann stated that one in eight of 12,000 of those returning home suffered from malaria.

Various races of *A. maculipennis* are found in Germany, *A. m. maculipennis* in the hills, *A. m. atroparvus* on the coast and in brackish waters, *A. m. messeae* in the interior, the second of these is the vector in East Friesland, the third in Berlin. H. Harold Scott

BATISTA, Djalma. O paludismo na Amazônia (Contribuição à epidemiologia, à protozoologia e à clínica estudo sobre a febre biliosa-hemoglobinúrica, síntese) [Malaria in Amazonia] 212 pp, 10 charts [Bibliography] 1946 Rio de Janeiro Imprensa Nacional

This volume on malaria in Amazonia is based almost exclusively on observations made in Manaus, the capital of the State. It is claimed that the nosology of the town is more or less typical of that of the whole vast State. Manaus is situated on the River Negro some 18 km from its confluence with the Amazon. Its population is about 65,000. It has a general hospital, *Santa Casa de Misericórdia*. About one-fifth of all admissions to that hospital are on account of malaria. Malaria cases occur throughout the year, but the maximum incidence is in the months June to October, the peak generally occurring in August. These are the months of minimum rainfall, highest temperatures and lowest humidities when water levels are at their lowest. Discontinuous collections of stagnant water provide very favourable conditions for mosquito breeding at this season.

Over a period of 22 years malaria has been responsible for 21.4 per cent of the total deaths in Manaus, and tuberculosis for 13.5 per cent. These two chief causes of death are not unrelated, debility caused by malaria predisposes to infection with the tubercle bacillus.

P. vivax infections predominate. A description is given of clinical forms of malaria seen and of rare forms of the disease. Curative and preventive treatment are also considered.

Though malaria is the chief endemic disease of Amazonia, work for the amelioration of conditions should not be concentrated on malaria alone but rather directed to an all-round improvement of sanitary conditions. Special geographical considerations and the scarcity of the population in this vast area necessitate special measures. Norman Whit

SENEVET, G. Nouvelles espèces d'Anophèles [New Species of Anophelines] Arch Inst Pasteur d'Algérie 1948, June, v 26, No 2, 149-61 [80 refs]

The author reviews the advances which have been made in the systematics of *Anopheles* in the ten years from 1938. In that period, eighty-seven new species

have been described of which in the author's opinion about seventy-three have good claims to be recognized.

The paper gives a list of the new species and varieties with the type locality of each, grouping them under sub-genera. A very large proportion of these new species are described from the tropics of the New World, twenty-one of them from Brazil. The author is of opinion that some of these new names are frankly synonyms and that others are of doubtful validity. He then proceeds to discuss the limits and synonymy of certain difficult groups of sub-genera, e.g. the perplexing American *Nyssorhynchus*. It is a matter of some interest that though many new species are described from the Old World sub-genus *Myzomyia* they fall easily into place in the existing scheme. This is not by any means true of some of the new American species. [It is suggested that the explanation is that owing to the careful scholarly work of EDWARDS, CHRISTOPHERS and others our knowledge of *Myzomyia* is well founded. In contrast with this, a fog prevails over *Nyssorhynchus* in the New World due in part to great natural difficulties but in part also to imperfect entomology. The position will grow worse if workers in tropical America are not prepared to exchange material, to take a wide international view and describe new species in comparison with what is already known.]

REID, J. A. A Preliminary Note on Malayan Forms of *Anopheles barbatirostris*. *Mal J Malaya*. 1947 Dec. v 2 No. 2, 1-5-7

The author produces evidence of the existence of at least two forms of *Anopheles barbatirostris* in Malaya. For the present, one is called the dark winged form and the second the light-winged form. Examination of material in the collection of the Institute for Medical Research, Kuala Lumpur suggested that the dark-winged form was typically a mosquito of the coastal plains, while the light winged form occurred both inland in hilly districts and on the coastal plain. Recent collections confirmed this. Some evidence of a circumstantial nature also suggests that the dark winged form is a fairly formidable vector of malaria, while the light winged form is relatively unimportant in this respect. Work is now in progress to determine this point.

EYLES, D. E., YOUNG, M. D. & BURGESS, R. W. Studies on Imported Malaria. 8. Infectivity to *Anopheles quadrimaculatus* of Asymptomatic *Plasmodium falciparum* Parasitemias. *J. National Malaria Soc.* 1948, June v 7 No. 2, 125-33, 1 fig.

Persons infected with *P. falciparum* often exhibit parasites in their blood in the absence of clinical symptoms of the disease. They are thought to be a particular danger to the community because of their liability unknowingly to infect mosquitoes. Over 2,000 *Anopheles quadrimaculatus* were allowed to bite 35 people in the asymptomatic stage of benign tertian malaria. The patients belonged to three categories: namely just prior to a relapse in between attacks and at the end of attacks. All three groups infected the mosquitoes. 28 per cent. of the batches became infected and 1 per cent. of the total mosquitoes. Mosquitoes which had fed on patients with symptoms of malaria became more heavily infected (half the total batches) which was only to be expected as the degree of parasitaemia in this group was higher than in the others. The authors showed that the infection in the mosquito was correlated both with the total parasite count and the male gametocyte count.

YOUNG, M D & BURGESS, R W Studies on Imported Malarias 9 The Comparative Susceptibility of *Anopheles quadrimaculatus* and *Anopheles maculipennis freeborni* to Foreign *Vivax* Malaria J National Malaria Soc 1948, June, v 7, No 2, 134-7

The infectivity of *P vivax* to two important anophelines of North America (*A quadrimaculatus* and *A maculipennis freeborni*) was compared under identical conditions. The strains of *P vivax* came from the Pacific, Africa, West Indies and Burma. In all, 921 *A quadrimaculatus* gave a 44.2 per cent infection rate, 830 *A maculipennis* gave a 52.7 per cent rate. The latter species also showed more numerous oöcysts. The relative susceptibility of 5 American carriers of this form of malaria was calculated to be as follows: *A maculipennis* — 100, *punctipennis* — 86, *quadrimaculatus* — 84, *pseudopunctipennis* var *pseudopunctipennis* — 35, and *albimanus* — 2. VARGAS, L & MATHESON, R Estado actual del *Anopheles earlei* Vargas 1943 y *Anopheles occidentalis* Dyar & Knab 1906 con claves para larvas pupas y adultos del llamado complejo *maculipennis* de Norteamérica [Position of *Anopheles earlei* and *Anopheles occidentalis* with Keys to the Larvae, Pupae and Adults of the *maculipennis* Group of North America] Rev Inst Salubridad y Enfermedades Trop Mexico 1948, Mar, v 9, No 1, 27-33, 6 figs on 2 pls [12 refs]

REY, H Revista de nuestros conocimientos sobre vectores de malaria en Colombia [Review of Known Malaria Vectors in Colombia] Tijeretazos sobre Malaria Venezuela 1947, Mar. & June, v 11, Nos 1/2, 30-32

The author reviews the position of the known vectors of malaria in Colombia proved by various investigators up to December 1946. A table shows the results of stomach and gland dissections of the species, together with the place and date of origin and the name of the workers reporting them.

The following species have been found to be naturally infected with plasmodia: *A darlingi*, *A punctimacula*, *A albitarsis*, *A pseudopunctipennis*, *A newai*. H J O'D Burke-Gaffney

PINOTTI, M, RACHOU, R G & FERREIRA, M O Algunos aspectos epidemiológicos de la malaria en el Litoral Sur del Brasil en la zona de transmisión por anofelinos del subgenero *Kerteszia* [Certain Aspects of the Epidemiology of Malaria in the South of the Coast of Brazil, in an Area of Transmission by *Kerteszia*] Tijeretazos sobre Malaria Venezuela 1947, Mar & June, v 11, Nos 1/2, 1-25, 10 text figs (3 maps) & 4 figs on 2 pls [26 refs]

[It will be remembered that in certain parts of Tropical America, where rainfall is high, large numbers of Bromeliad plants grow on limbs and trunks of trees. They hold water among their leaf bases, and *Anopheles* of the specialized subgenus *Kerteszia* breed in them.]

In the extreme south of Brazil, in parts of the States of Parana, Santa Catalina and Rio Grande del Sul, one finds abundant Bromeliads and three species of *Kerteszia*, *bellator*, *cruxii* and *homunculus*. The paper discusses their biology and methods which have been used for destroying Bromeliads and to control mosquitoes. The area is malarious, but it cannot be accepted that the infections are to be attributed solely to the *Kerteszia*. P A Buxton

i From a study of the literature it would appear that the tissue changes occurring in malaria infections are of two types (1) continuously progressive and (?) periodic. Anoxaemia, vascular and circulatory disturbances are associated with the first of these the malaria paroxysms with the second.

Anoxaemia results from defects in pulmonary ventilation and blood circulation, and from red cell destruction with consequent deficiency in oxygen carrying capacity of the blood parasitic invasion of the red cells and intra-vascular red cell agglutination with the formation of "sludge" (HAXELL *et al.* see this Bulletin 1943 v 40 584), a result of the generalized anoxia, add to this.

During the cold stage of a malaria paroxysm there is peripheral vascular constriction, a rise in blood pressure, and slowing of the circulation time. During the hot stage there is peripheral dilatation and a fall in blood pressure with increased cardiac output. The heart rarely fails, but a condition of medical shock may result from generalized vascular collapse with loss of circulating blood volume, indicated by an increased cell count and haemoglobin concentration.

Local circulatory changes are influenced by the vascular anatomy of the organs concerned, or by reflex reactions. Reflex vascular mechanisms are known to exist in the kidney and in the liver lobules. Mechanical obstruction to circulation occurs in some tissues as a result of swelling of the vascular endothelium, with an accumulation of leucocytes, parasitized red cells and debris. True thrombosis may occasionally occur. A local loss of fluid from circulating blood, with impaction of the red cells is a major factor in the production of vascular stasis. This takes place particularly in organs with capillaries normally impermeable to protein as the brain and the heart and the result is a local tissue anoxia.

The generalized circulatory changes during a malaria paroxysm are probably of central origin and may be due to stimulation, and possibly concomitant inhibition, of certain vasomotor centres, especially in the hypothalamus attributable to the release of a diffusible substance during parasitic proliferation. Loss of body fluid by sweating and diarrhoea is a minor contributory factor. Changes in the vascular endothelium are evident histologically and by induction on physiological grounds. Tissue anoxia is probably a factor in their production. Evidence is forthcoming that any malarial toxin plays a part in their causation. The consequent increase in permeability of the affected vessels allows protein and fluid to escape into the tissues.

In the brain, anoxia due to progressive capillary stasis leads to degenerative changes and necrosis of surrounding tissue. The cerebral lesions of malaria are not peculiar to the disease but occur in other conditions, as severe anaemia, hyperthermia, mechanical obstruction of the large vessels to the brain, and narcotic poisoning. The stasis or near stasis seen in the cerebral capillaries is temporary and reversible. It is not associated with true agglutination or clotting of the involved red cells. On resolution of the stasis the escape of protein through the vessel wall stops and with the return of fluid circulation through the vessel recommences.

While vascular stasis is common in the brain it is uncommon in the liver and it may or may not occur in other tissues. Variations in the permeability to protein of the endothelial cells of the vessels in the various organs may afford

to unpublished data which show that *P. falciparum* persist apparently unaltered for at least 18 hours but that they have vanished by 36 hours after death.

Dr MARGATROYD suggested that if changes in the permeability of the cerebral vessels in malaria permit the escape of protein through them an increase in the protein content or volume of the cerebro-spinal fluid would be expected. This does not consistently occur. Dr NICOL stated he had occasionally seen cases of peripheral circulatory failure in cases of *P. vivax* infection the condition persisted for several days after specific antimalarial treatment. Lt.-Col. MAXTOLD reported a case of *P. vivax* infection with extraordinary hyperpyrexia and a dry theca, which at post mortem showed blocking of the choroidal plexus by parasitized cells.

MARGATROYD in reply referred to the lesions occurring in the suprarenals and the pituitary and their relation to the pathology of malaria. He reaffirmed that on a study of the literature there was little evidence for including cardiac failure as a common complication of malaria. It is vascular collapse rather than cardiac failure which is the commoner cause of death the two are often confused.

A. R. D. ADAMS

JASSIAS, C. A propos des fausses réactions de la syphilis dans le paludisme [False Positive "Syphilis Reactions" in Malaria.] *Bull. et Mém. Soc. Méd. Hôp. de Paris*, 1948, Vol. 24/25 824-8.

The author discusses briefly the false positive serological reactions encountered with the use of different tests for syphilis in persons suffering from malaria. In 25 years experience he has examined tens of thousands of sera from malaria patients, and has never found the Hecht reaction positive (nor in leprosy) provided that the technique is accurate and the reagents carefully controlled. He finds an antigen made from human heart the best. Occasionally the Hecht reaction was positive but transient during the eruptive stage of measles.

H. J. O'D. BURKE-GAFFNEY

BROOME, M. M. & DONALDSON, A. W. Transfer of Malarial Parasites between Blood Films during Mass Staining Procedures. *Pub. Health Rep. Wash.*, 1948, July 30 v. 63 No. 31 991 1004 2 figs.

This paper must have given many field malarialogists "furiously to think." The authors appear to have demonstrated the danger of false "positives" when slides are stained in bulk for the detection of malarial parasites.

Were the methods employed in these experiments widely used in malaria surveys, they would appear to invalidate many of the published reports. In order personally to check the results the reviewer stained batches of slides put up by the method described and was satisfied that transfers of blood did actually take place from slide to slide in a varying proportion of cases.

On the other hand, such transfers were not detectable when mixed infected and non-infected or mammalian and a human blood slides were stained together in the upright position in ordinary staining dishes where the distance between neighbouring slides is considerably greater than when the slides are tightly separated by pieces of cardboard at one end as in the technique used in the experiments under review.

In the latter case the separation is so small that actual contact between neighbouring slides is easily brought about by the handling necessary in the staining, manipulations or even in putting up the packs of slides. One may say therefore that the danger of transfer of blood from one slide to another has been proved by the authors under the conditions of their experiments but that this

does not invalidate previous survey results obtained by other methods of bulk staining [For the experimental methods employed, the reader is referred to the detailed description in the text] H E Shortt

IPF, H F Zur klinischen Brauchbarkeit der Melaninserumreaktion von Henry bei der Malaria (Modifikation nach Trenz) [The Clinical Value of Trenz's Modification of Henry's Melanin Reaction] *Klin Woch* 1948, May 1, v 26, Nos 17/18, 274-6, 3 figs [12 refs]

If direct examination of the blood by the thick drop method fails to reveal malaria parasites, there is need for some diagnostic means for existent or latent malaria. Twenty-one years ago Henry brought out his iron albuminate serum reaction, later the melanin reaction for serological diagnosis, but the fact that a similar reaction was given in several other diseases, such as tuberculosis, carcinoma, syphilis, leprosy, typhoid fever, pernicious anaemia and kala azar robbed it of most of its value. The author discusses this and Trenz's photometric modification of the original test and shows that readings of over 56 are alone of practical use and that below this the test is not reliable. Comparing the melanin-serum reaction (macroscopic and photometric readings) with the water flocculation reaction, he found a parallelism between them, the sera remaining clear or showing mere turbidity are to be regarded as negative, those giving precipitation as positive, i.e., with photometric value of 56 or over. In latent malaria one may find lower levels, in such it is not so much the height of the reaction as its movement [variations], therefore a series of tests should be taken and the results plotted, if we are to obtain results of diagnostic and prognostic value. For the rapid diagnosis of malaria, consequently, the melanin-serum reaction is not to be relied upon. H Harold Scott

COURVÈS, J M Paludisme viscéral évolutif à symptomatologie cérébro-méningée [Malaria with Visceral Development of the Parasites and Cerebral and Meningeal Symptoms] *Bull Soc Path Exot* 1948, v 41, Nos 5/6, 368-71

BARASCIUTTI, A & DE NEGRI, U Nefropatie in malarici [Renal Disease in Malaria] *Acta Med Italica* 1948, May, v 3, No 5, 117-22 English summary

This paper contains a description of twelve cases of malaria in which concomitant renal disease was the outstanding characteristic. Nine presented signs and symptoms of acute glomerulo-nephritis, one of lipoidal nephrosis and two of chronic nephritis with uraemic syndrome. Eleven of the patients were infected with *P vivax*, one with *P falciparum*. The literature concerning the association of renal disease with malaria is considered at some length and the authors conclude that malaria may cause nephritis particularly in patients predisposed to renal disease. Many of the authors' patients come from the delta of the Po where they live in damp, insanitary dwellings, and are ill-nourished and underfed. Specific malaria therapy promptly produced a marked improvement, or disappearance, of renal symptoms. Norman White

DELANOE G Sur un cas de purpura hémorragique de nature paludéenne [A Case of Haemorrhagic Purpura due to Malaria] *Bull Soc Path Exot* 1948, v 41, Nos 5/6, 364-8

PERVIZ, M. Réactivation et traitement des formes chroniques de l'amébiase et du paludisme. [Reactivation and Treatment of Chronic Amoebiasis and Malaria.] *Rev. Paludisme et Mtd. Trop.* 1948, July Aug. Sept. v. 4 Nos. 50 51 & 52, 197-205.

A chronic concealed reticulo-endothelial type of infection with *P. falciparum* is described and the means of its revelation and treatment are discussed. Intravenous emetine and strychnine injections are advocated in the therapy of amoebiasis.

A. R. D. Adams

MOXK, J. F. Modern Therapy of Benign Tertian Malaria. *Brit. Med. J.* 1948 June 23 1221 5 1 chart. [16 refs.]

This review of recent developments in the treatment of *P. vivax* malaria is summarized by the author as follows:

"The ideal drug for the prevention and radical cure of benign tertian malaria has yet to be discovered.

"The disease of unaided quinine therapy is recommended.

Suppressive and curative treatment with mepacrine is likely to be superseded by more recently discovered antimalarial drugs.

"Paludrine and chloroquine are probably equally effective in producing complete suppression of overt attacks of malaria in once-weekly dosage. Neither is able to prevent the establishment of *P. vivax* in the human host even by daily dosage, but paludrine has some inhibitive effect on the pre-erythrocytic forms. Neither drug given alone is as successful as other forms of therapy in producing a low relapse rate.

"Pamaquin is a drug which deserves greater recognition as a safe medium for the elimination of *P. vivax* infections. Given as an adjunct in any course of antimalarial therapy it is of the greatest value in reducing the relapse rate. The toxicity of pamaquin is shown to be less formidable than is generally accepted.

No treatment so far administered to a large series of cases of naturally occurring B.T. malaria is more successful than quinine given concurrently with pamaquin. Paludrine given concurrently with pamaquin is equally successful.

Pentaquin given concurrently with quinine is likely to prove more successful in producing a lower relapse rate than any other therapeutic regime. The toxicity of pentaquin is approximately three quarters that of pamaquin.

"A 31-days intermittent course of quinine and pamaquin proved successful in the complete eradication of *P. vivax* infections in all patients followed up in a series of 45 cases. It is suggested that such a course is worth extended trials among chronic relapsing cases in a non-malarious area.

PARSON, L. G. Blood and Bone Marrow Concentration of Atabrine and its Role in Aplastic Anemia. *J. Lab. & Clin. Med.* 1948 July v. 33 No. 7 627-32.

Rabbits were given an intramuscular injection of 8 mgm. per kgm. of mepacrine (atabrine) dihydrochloride. They were killed at intervals and the distribution of mepacrine was examined: the results are shown in Table I.

There was still a considerable amount of mepacrine in the bone marrow on the 4th day, by which time the plasma, erythrocytes and leucocytes of the peripheral blood contained hardly any. In chickens treated in the same way the distribution at 4 hours was similar to that in rabbits; by the fourth day all the tissues were free from mepacrine except the liver and spleen, which contained

| Spleen | 40.62 | 1.96 | 0.44 | 0.11 |

small amounts. Although the erythrocytes of fowls are nucleated, the concentration of mepacrine in them was less than a third of that in the leucocytes, apparently the high concentration of mepacrine in leucocytes does not depend principally on the presence of a nucleus.

Further experiments were made on five patients with the results shown in Table 3.

TABLE 3

*Blood and bone marrow concentration after oral administration of atabrine dihydrochloride to five patients **

| Patient | Condition | Leucocytes per cmm | Atabrine level ($\mu\text{gm} \times \text{liter}$) | | | |

* Doses varied so that absolute levels between patients are not comparable.

Although the marrow specimens were greatly diluted by peripheral blood, the concentration of mepacrine in them was high. In a discussion of these findings, it is concluded that the alleged relationship between mepacrine and aplastic anaemia is not a direct one, rather it seems to depend on idiosyncrasy.

F. Hawking

SINGH, I. *Mepacrine Dermatitis*. *Brit J Dermat & Syph* 1948, Mar, v 60, No 3, 90-105, 4 figs [13 refs]

¹Eighty-three cases of atypical lichen planus associated with suppressive mepacrine are described. The patients were all males, the majority were

aged between 21 and 35 and were employed as labourers on the Burma front mostly in a civilian capacity. Sixty-three had taken an average daily dose of 0.1 gm. mepacrine for 3 to 24 months; the remaining 20 had taken a larger dose for a shorter period.

In 73 per cent. of the cases the onset of the dermatitis was acute with a generalized erythema followed in 24 to 48 hours by crops of red itching papules. Later manifestations were follicular hyperkeratosis, papules, plaques and verrucous nodules.

Less commonly the onset was insidious, with glossitis, pigmentation of the mouth and tongue, a pigmented macular rash, pruritus, desquamation, or follicular hyperkeratosis. In four cases the eyes were involved, pigmentation of the conjunctiva and conjunctivitis being observed, and in one case corneal ulceration resulting in blindness. Scalp lesions were uncommon, and no case of permanent baldness was seen. The nails were not infrequently affected.

The biological picture showed acanthosis, an increase in the stratum granulosum, hyperkeratosis, parakeratosis, and sometimes spongiosis. There was increased vascularity in the papillae and the sub-papillary layer with considerable perivascular cellular infiltration. A pigment distinct from melanin and resembling mepacrine was seen both as free granules and within the phagocytes, especially in the papillary areas and around sweat glands.

In an attempt to establish the aetiology of this condition, the author observes that no case of similar dermatitis was seen in any person who was not taking suppressive mepacrine. He was able moreover to produce exacerbation of the condition by giving mepacrine to the affected patients, and to reproduce it in normal subjects by giving the drug in a dose of 0.4 gm. daily for 17-32 days.

The severity of the disease appeared to be related to the amount of mepacrine stored in the skin. The result of a prolonged course of mepacrine was to produce a slow rise in the skin mepacrine level, which fell more slowly than the plasma mepacrine after the drug had been discontinued. In general the disease was most severe in patients with low body weight, the severest cases being met with in patients weighing between 84 and 102 lb. Dosage should therefore be determined by body weight rather than age.

Treatment was designed to secure rapid elimination of the drug by giving fluids and by increasing the acidity of the urine. The nutrition was improved with a high protein diet and added vitamins. Generally it was advisable to remove patients to a cooler climate. [See also this Bulletin 1947 v 44 499-503.]

EL DIN NOUR EL DIN G. Toxic Psychosis as an After Effect of Atabrin.
J. Roy. Egyptian Med. Ass. 1948, June v 31 No. 6, 489-500 [15 refs.]

The author in 1933 saw a medical student who developed mania with delirium and hallucinations after intravenous atabrin (mepacrine). He recovered within a few days. In 1944-45 atabrin was used on a large scale for malaria treatment at the research institute, Cairo: three patients showed mental symptoms (two of these three had the drug parenterally). The drug is now used as a tannicide: a single dose of eight tablets is given, followed an hour later by a purge. No mental symptoms have resulted from this treatment. Very recently atabrin has been tried as an amoebicide: 3.5-4.5 gm. being given in 5 days. No mental symptoms have resulted in the 35 cases so treated.

Some details are given of the three patients who developed toxic psychoses while under antimalarial therapy, and the literature on the subject is touched on. [See also this Bulletin 1948, v 45 600.]

LUCENA, D T Tratamento da malária pelo aralen [Treatment of Malaria by Aralen] *Rev Brasileira Med* Rio de Janeiro 1948, Apr, v 5, No 4, 269-79, 4 graphs English summary

Aralen is chloroquine diphosphate This paper is already so condensed that abstraction is hardly possible The total number of patients treated was small, 83, of whom 40 were adults and 43 were children Infections were by all three malaria parasites and the criterion of cure was disappearance of clinical symptoms and failure to find the parasites in thick smears on three consecutive occasions Adults were given total doses of 1.5-2 gm (occasionally 2.5 gm) in divided amounts spread over 1-3 days The 43 children were divided into four age-groups 0-4 years, 4-8, 8-12 and over 12 years and for these nine different regimens of treatment were tried The results can, therefore, only be summarized briefly (1) *P vivax* infections, clinical symptoms cleared up in 24 hours and parasites in the same time in four-fifths, and in two days in the rest [would not this occur naturally in *P vivax* infection?] (2) *P falciparum*, clinical symptoms again cleared up in 24 hours and trophozoites disappeared from the blood, gametocytes persisted for several days (3) *P malariae*, clinical symptoms cleared, as with the other parasites, in 24 hours, but the plasmodia were found for a little longer than in the case of *P vivax* but not so long as *P falciparum* In the above dosage there was no sign of any toxic action of the drug

SIMMS, B R & KIKER, C C Temporary Dewatering in applying Deepening and Filling to permanently eliminate Mosquito Breeding Areas in Tennessee Valley Authority Impounded Reservoirs *J National Malaria Soc* 1948, June, v 7, No 2, 100-108, 6 figs

The problem of malaria transmitted by *A quadrimaculatus*, which breeds in waters along the margins of reservoirs in the Tennessee Valley, is dealt with by permanent elimination of the breeding areas, this involves two methods —

(a) Deepening and filling, (b) Diking and dewatering
These methods have been described by BISHOP and GARTRELL, this *Bulletin*, 1945, v 42, 184

Dewatering involves the installation of a permanent pumping station with attendant recurrent annual costs, moreover, for control of mosquito breeding, this method is not as satisfactory as deepening and filling This paper describes the initial use of temporary diking and dewatering to facilitate deepening and filling procedure under favourable engineering circumstances, the cost of the temporary measures in this instance were 5-10 per cent of the total deepening and filling project It is believed that this temporary dewatering method, by means of specially designed pumps, will be widely used to extend deepening and filling projects

R Ford Tredre

By exposure of caged mosquitoes to similar sprayed surfaces it was determined that 4 and 5 per cent concentrations still produced rapid kills of *quadrimaculatus* 69 and 68 days after application of the insecticide. The lesser concentrations were not so satisfactory.

Application of residual insecticides in one anopheline shelter reduced the numbers of *quadrimaculatus* in adjacent similar shelters. These field experiments were conducted during 1946 in the vicinity of a reservoir in South Carolina, U.S.A.

ELMENDORF, J. E., Jr. assisted in Field and Laboratory Operations by L. G. BARNHILL, M. T. HOCKENGA & M. TAKOS. Second and Supplementary Report on Field Experiments to demonstrate Effectiveness of various Methods of Malaria Control. *Amer J Trop M J* 1948, May v 28 No. 3 45-53.

This paper should be read together with a previous one [this *Bulletin* 1947 v 44 882] recording survey results and techniques used. Five villages in tropical America in which malaria was endemic and carried by *Anopheles albimanus* were subjected to an initial survey over a period of nine months and then used for a comparison of the values of different control methods. Treatments were started in December 1945 except that in the first village treatment with oxychloroquine [no further description given] was started in April 1946. The effect on the spleen and parasite rates is summarized in the following table in which S.R. means spleen rate and P.R. parasite rate.

| Control method used | | Survey result | | | | | | | | |
|----------------------------|------|---------------|------|------|------|-----|------|------|------|--|
| | | 1945 | | | 1946 | | | | | |
| | | Apr | Aug | Dec | Apr | May | July | Aug. | Dec | |
| Oxychloroquine prophylaxis | S.R. | 68.3 | 93.6 | 92.9 | 93.3 | | | 66.7 | 61.9 | |
| | P.R. | 41.8 | 8 | 82.3 | 41.0 | | 12.5 | 26.7 | 5.9 | |
| DDT residual spray | S.R. | 92.5 | 93.7 | 94 | 74.2 | | | 81.3 | 62.5 | |
| | P.R. | 44.2 | 45.6 | 97.1 | 36.3 | | | 24.4 | 15.6 | |
| Aircraft antilarval DDT | S.R. | 91.6 | 87.7 | 90.7 | 86.6 | | | 84.4 | 64.8 | |
| | P.R. | 31.1 | 54.7 | 83.4 | 61.4 | | | 34.7 | 12.7 | |
| Chloroquine prophylaxis | S.R. | 90.7 | 92.7 | 97.9 | 8.9 | | | 69.0 | 36.8 | |
| | P.R. | 33.1 | 38.3 | 47.6 | 6.0 | 5.4 | | 9.3 | 2.1 | |
| No treatment | S.R. | | | | 94.8 | | | 94.3 | | |
| | P.R. | | | | 39.6 | | | 16.6 | 57.6 | |

The cooperation received in the village where oxychloroquine was used as a prophylactic was much less than in that where chloroquine was used, and comparison is not possible. In assessing results comparisons should be made between findings in the equivalent months in the treated and untreated periods. Notable features are the marked lag before the drop in the spleen and parasite rates in the villages where DDT was used as either a larvicide or an adulticide and the eventual production of highly satisfactory results. One single treatment with DDT as a residual spray produced this result whereas many personal applications were made of DDT as a larvicide from aircraft (though it is not shown that this was necessary). The authors conclude that a very satisfactory result can be obtained by one annual treatment with DDT residual spray in which a 5 per cent solution of DDT in kerosene is applied at the rate

WHITMAN, L The Prolonged Viability of Sporozoites of *Plasmodium gallinaceum* in Extracts of Washed Chicken Erythrocytes J Immunology 1948, July, v 59 No 3, 285-94

Experimental malarology has been handicapped by the absence of a suitable medium in which to retain sporozoites for injection into clean animals. Even in the fluid (heparinized plasma) recommended by TONKIN [this Bulletin, 1948, v 45, 243] the survival rate was not extended much beyond 24 hours. Whitman, however, has discovered a better medium which will prove of great value to workers in this field. It is an extract of chicken erythrocytes prepared in the following way. Heparinized chicken blood is centrifuged for 20 minutes at 2,500 r p m, the plasma is withdrawn and the cells are suspended in 4 times their volume of saline, and recentrifuged. The washing is done twice more and then the cells are centrifuged with a minimum of saline at 3,500 r p m for 30 minutes in order that their exact volume might be found. The cells are resuspended in four times this volume of saline and transferred to an Erlenmeyer flask of such size that the suspension lies one inch deep. It is then frozen in a dry ice chest, thawed at 37°C (warm water) and refrozen for another hour. It is thawed again and centrifuged at 3,500 r p m for 30 minutes to remove the debris. For use, this extract is diluted 1 in 10 with physiological saline and the diluent is used both as a fluid in which to dissect the mosquito's glands and for storing the sporozoites.

It was shown that few *P. gallinaceum* sporozoites died in this fluid during the first 24 hours and many lived up to 72 hours, even at 25°C. The addition of penicillin (500 units per cc) is said to have no adverse effect on the sporozoites [but the experiments were not done on a quantitative basis, and it is possible that only a proportion survived this treatment]. An interesting observation was made on the inhibitory effect on sporozoites of extracts containing mosquito thoracic tissue. Two birds out of six failed to become infected and in the remaining four, the incubation period was prolonged. [It is desirable that this work should be confirmed on a larger scale, because if it is so confirmed, it would require that sporozoites used for infection purposes should be obtained from dissected glands only and not from ground-up thoraces, which is a common method at present.] P C C Garnham

DESCHIENS R & PICK F Sur la non-inoculabilité de l'embryon de la poule domestique par le sang infecté par *Plasmodium gallinaceum* Brumpt 1935 [Failure of Blood Infected with *P. gallinaceum* to Infect Chick Embryos] Bull. Soc Path Exot 1948, v 41 Nos 5/6, 353-6

JOHNSON, H A & AKINS, H The Effect of One Plant Extract and of certain Drugs on the Development of *Plasmodium gallinaceum* in *Aedes aegypti* J National Malaria Soc 1948, June, v 7, No 2, 144-7

Various substances were tested on *Aedes aegypti* to observe their effect on *P. gallinaceum* infections. The tests were performed by allowing the mosquitoes, throughout the period immediately after emergence to 14-20 days after the infective blood meal, to feed on cotton sponges moistened with 2 per

cent. sugar solution plus the test drugs. The following had slight or no effect on the development of sporozoites —

Atabrin dihydrochloride—0.15 gm. 1.3 gm. per litre.

Plasmoquine naphthoate—11.2-67 mgm. per litre.

Chloroquine base—0.5-2 gm. per litre.

Red clover extract—filtrate from 14 blossoms in 100 cc.

The following substances exerted a very marked inhibitory action —

Quinine sulphate—0.67 gm. 1.33 gm. per litre.

Paludrine hydrochloride—0.18 gm.—0.435 gm. per litre.

In one experiment paludrine was withheld until the sporozoites appeared in the gland and the drug was then given for 5 days: no lethal effect on the sporozoites was observed after this delayed administration. Most of the drugs had some toxic effect on the mosquitoes and the results suggested that if higher doses could have been tolerated an inhibitory action on the sporozoites would have resulted. Chloroquine base was very toxic to the mosquitoes and showed little effect on development of sporozoites. P. C. C. Garnham

BISHOP Ann & BRACKETT Betty. Drug-Resistance in *Plasmodium gallinaceum* and the Persistence of Paludrine-Resistance after Mosquito Transmission. *Parasitology* 1948, July 39 Nos. 1/2, 1-5-37 [32 refs.]

A preliminary account of these experiments on the production of drug resistance in *P. gallinaceum* has been given by the authors [this Bulletin 1947 v. 44 869]. For this purpose they maintained a patent infection in young chickens by giving intravenous inoculations of heavily infected defibrinated blood at intervals of 24 to 48 hours in order to avoid the influence of exo-erythrocytic forms. The drug was given orally in aqueous solution on the day before inoculation and at least once per day thereafter proportional to the weight of the bird. Dosage was such that multiplication of erythrocytic forms was not interfered with. Tests were made at intervals on the normal and treated strain of *P. gallinaceum* to find if resistance had developed. In the case of atabrin (mepacrine) natural resistance to the drug was not increased after 6 months continuous treatment. With plasmoquine (pamaquin) a slight but definite resistance was detected after 8 months treatment. In the case of paludrine on the other hand, a forty fold increase of resistance was observed and was not lost after five serial passages through the mosquito vector. By the use of inocula, consisting mostly of exo-erythrocytic forms, from the pulsed spleen of a paludrine-resistant bird, it was shown that the exo-erythrocytic forms which arise from a resistant strain are themselves resistant to the drug, as are also the erythrocytic forms derived from them. Resistance to paludrine involved also resistance to a methyl derivative of the drug (M-4440) but not to mepacrine or pamaquin. The immunological relationships of the normal strain were unaltered after it had been made resistant to paludrine.

THOMPSON P. E., MCGILVER D. A., BISH D. L. & WILSON Mary L. Radioactive Dicks and Canaries and its Effects on their Initial Malarial Infections. *J. Inf. & Dis.* 1948, July Aug. 83 No. 1 23-32, 2 figs. 11 refs.]

Radioactive colloidal iron mixtures containing Fe^{59} and Fe^{55} with half life period of 44 days and 4 years respectively were administered parenterally to ducks infected with *P. malariae* and canaries infected with *P. catenellum* in doses near the maximum tolerated to determine whether the radiation emitted (β and γ rays) had any effect on the multiplication of parasites. Radioactivity

of blood and tissues was measured by means of a Geiger-Mueller tube after digestion with acids followed by electro-plating of the iron on tinplate. In order to promote utilization of the injected radio-iron, the birds were rendered iron-deficient. Infection was produced by intravenous inoculation of blood. It was found that the iron injected intravenously or intraperitoneally was readily taken up by blood cells, but was more slowly converted to haemoglobin when given by the latter method. Before determination of the amount of radioactive iron in tissues of treated birds, blood was repeatedly withdrawn and replaced by normal citrated blood and saline and in addition the tissues were washed in water. Liver, spleen and bone-marrow contained the greatest amounts of the active material. Radio-iron was also detected in the excreta of canaries after intravenous administration of the substance.

Histological examination failed to reveal damage to organs or leucocytes due to radiation. There was no significant difference in the survival rates of birds receiving natural iron or radio-iron and any toxic effects appeared to be due to the metal itself rather than to radiation emitted. Radio-iron did not affect the course of *P. cathemerium* infections in canaries or of *P. lophurae* infections in ducks, as judged by parasitaemia and morphology of the parasites, in spite of the fact that the accumulation of pigment in the schizonts permits the maximum exposure to radiation during division.

J D Fulton

PIEKARSKI, G. Experimentelle Untersuchungen zur Frage der Atebrinfestigkeit der Malaria-Parasiten [Experimental Investigations concerning Mepacrine (Atebrin)-Resistance of Malaria Parasites] *Ztschr f Hyg u Infektionskr* 1948, Apr 1, v 127, Nos 6/8, 501-11 [14 refs]

Canaries were infected with *P. cathemerium*. When parasites appeared in the blood, the birds were treated daily with subeffective doses of mepacrine. The infection was then transferred to two new canaries which were similarly treated, and so on for 27 passages during 10 months. At intervals, the sensitivity of the parasites was compared with those of the original untreated strain. The strain treated with mepacrine never became more resistant to mepacrine than the normal strain, in contrast, there was some evidence suggesting that it might be more sensitive. This work was done during 1944. [WILLIAMSON and LOURIE (this Bulletin, 1948, v 45, 48) found that *P. gallinaceum* did not become resistant to mepacrine when exposed to it *in vivo* for a very long period, it did, however, become resistant to paludrine quite readily.]

BECKMAN, H. Infectivity of Sporozoites of *Plasmodium cathemerium* 3H2 exposed *in Vitro* to Hen and Canary Bloods. *Proc Soc Exper Biol & Med* 1948, Feb, v 67, No 2, 172-6

Previous work had shown that a strain of *P. cathemerium*, maintained since 1937 in mosquito-canary-mosquito passage, was unable to infect the great horned owl, guinea pig, fowl or man. The present experiments were devised to discover whether chicken's blood was lethal to sporozoites of this species *in vitro*. Heart blood was taken from uninfected canaries and from hens. Clotting was prevented by heparin or sodium citrate and the blood was retained in an incubator at 41.5°C until the sporozoite suspension was ready to seed. The sporozoites were obtained by triturating infected *Culex pipiens* mosquito in Locke's solution and filtering the product through three layers of gauze, the sporozoites appearing in the filtrate. Exactly similar amounts were then added to the canary and hen blood respectively (so that 0.05 cc of the mixture would contain the sporozoites from 1 mosquito). The mixtures were agitated

in the incubator and samples were removed at 30-minute intervals up to 7½ hours, for inoculation into canaries.

The results were clear cut. 78 out of 80 birds inoculated with the parasite in canary blood developed the infection (the incubation period being delayed after the longer exposures in the incubator) while only two out of 8 birds inoculated with the sporozoites in chicken blood subsequently developed the infection. It was thus shown that the blood of the hen exerts an inhibitory action upon the sporozoites of *P. calhemerium* *in vitro*. P. C. C. Garnham

TRY PANOSOMIASIS

HORNBY H. E. Report on the Tsetse-Fly Problems of Maputo. In, *Inst. Med. Trop. Lisbon*. 1947 Dec. v 4 313-71 15 figs. on 9 pls. & 1 folding map.

This is the author's final report on the tsetse fly and trypanosomiasis of the Maputo district and is intended to supersede two earlier ones. It deals with trypanosomiasis of cattle and *Glossina brevipalpis*.

Maputo is the most southern district in Mozambique and lies between Swaziland and the Indian Ocean. It is a most important region because of its relationship to Lourenço Marques. The physiography and climate are briefly described. rainfall is usually more than 100 cm. and falls mainly between October and April. approximate temperatures (in C.) are 18 to 38 from October to December 5 to 28 from May to July and from 10 to 31 in April. The vegetation is described in detail and is discussed in its relation to *Glossina brevipalpis* with a short reference to *G. ussuriensis*.

There are about twelve plant communities grouped into five types: (1) climax (and near-climax) forest and bush, which provides conditions suitable for the breeding of *G. brevipalpis*; (2) tidal swamp vegetation and (3) grassland, both of which are tsetse feeding grounds; (4) acacias, which are sometimes unfavourable to tsetse though this depends on the nature and incidence of bush clumps; and (5) mixed bushland, where if there is a dense population and little stock, *G. brevipalpis* does not occur but if the people have moved away and game has returned, bush clumps exist which are suitable breeding places. More than 400 common woody plants of the district are listed with notes on the kind of plant and type of habitat. Some of these are illustrated by photographs.

Glossina brevipalpis occurs throughout a large part of Maputo, but its exact extent is unknown. It has been taken in many places from the Zululand border to a few miles north of the Bela Vista-Changalane road; the greatest numbers were taken along the river itself. The fly is most active after sunset and it is almost certain that it prefers to hunt by night. Pupae are found close to a good feeding ground, in sites which are not exposed to full sunlight and never waterlogged. Such conditions are usually found under a double but not necessarily thick canopy. Release and recapture experiments showed that the species is a very strong flier and often travels several kilometres in one night. Some evidence was also obtained of the decline in numbers during the dry season. Most were taken between February and May and fewest in September. Cattle and other domestic animals, as well as game animals, are occasionally attacked during the daytime but this is not the usual way in which *G. brevipalpis* gets its blood meals. The hippopotamus appears to be the most important and reliable source of food especially when these animals lie near evergreen forest or bush which affords resting and breeding sites for the fly.

A trypanosomiasis survey of apparently healthy domestic animals showed that a large proportion of adult animals possess much immunity. Out of

Vol 45, No 12]

10,880 cattle, 1,256 goats and 31 donkeys, 10-15 per cent of the bovines and 1-83 per cent of the goats were shown to be harbouring trypanosomes, of the positive smears, 67 per cent showed *T vivax*, 16 per cent *T congolense* and 17 per cent mixed infections of both. An experiment with *G brevipalpis* and imported *G morsitans*, to determine whether the species of tsetse had anything to do with the mildness of the cattle trypanosomiasis in Maputo, left the matter undetermined because of the failure to induce *G morsitans* to feed. Of the 72 *G brevipalpis* which fed on infected animals, 50 per cent showed some development of trypanosomes, in 11 flies (15.3 per cent) the labial cavity had been invaded and 4 flies (5.5 per cent) became positively infective with trypanosomes in the hypopharynx.

The mildness of the trypanosomiasis in Maputo is due, in the author's opinion, to the smallness of the herds and to the good and adequate food, and possibly to an acquired immunity reinforced by subsequent infections. Though the existing conditions are far from satisfactory he considers that it would be better not to interfere unless the contact between fly and cattle could be broken completely.

In an attempt to discover whether this could be done, two experimental clearings are being made and studied. In the first, the intention is to turn all bushland into grassland with scattered trees. The second clearing adjoins the first, and here the main object is to attack all breeding sites, to ascertain and afterwards to demonstrate the kind of work which will have to be done outside settled areas in order to permit expansion as more land is required for settlement. At present, each of these areas is less than 1,000 acres, and together they are too small to safeguard the contained animals from *G brevipalpis*, but they may show that flies caught inside are transitory invaders and if the first clearing can be extended to a full-size settlement protected by a second, it is hoped to show that it is possible to make an area fly-free and prepare it for intensive settlement. The author has been able to supervise only the beginning of this experiment.

In a short reference to *G austeni* only two foci of this species are described. They are both on the Changalane river where a few flies have been taken. Before economic methods of control can be worked out much more must be known about the distribution and bionomics of this species of tsetse fly.

FERREIRA F S da C Sobre o grau de infestação por tripanosomas da *Glossina palpalis* da Guiné Portuguesa [The Degree of Infestation of *Glossina palpalis* by Trypanosomes in Portuguese Guinea] *An Inst Med Trop* Lisbon 1947 Dec v 4 91-7 English summary

1 FERREIRA F S da C Relatório do Chefe da Missão de Estudo e Combate da Doença do Sono na Guiné referente a 1945 [Report of the Sleeping Sickness Survey of Portuguese Guinea for 1945] *An Inst Med Trop* Lisbon 1947, Dec v 4 713-49 14 figs (1 map)

II FERREIRA F S da C Relatório do Chefe da Missão de Estudo e Combate da Doença do Sono na Guiné referente a 1946 [Report of the Sleeping Sickness Survey of Portuguese Guinea for 1946] *An Inst Med Trop* Lisbon 1947 Dec v 4 751-89 7 figs (3 maps) & 3 pls

These papers constitute a report of the organization of the campaign and the results of a year's work (1947)

Pinto A. R. O recenseamento dos doentes do sono. (Extracto dos relatórios semestrais referentes ao ano de 1946) [Sleeping Sickness Survey Half-yearly Reports for 1946.] *Im. Inst. Med Trop* Lisbon, 1947 Dec., v 4 791-810 7 figs. (1 map).

This record applies to a part of Portuguese Guinea, depicted in a line map with an area of 45,000 sq. kilometres and a population of 110,000. The people were collected, with the aid of local chiefs, and specimens were taken of gland-juice, blood and cerebrospinal fluid, to confirm suspicious clinical diagnosis, the gland-juice method especially. Between the 1st March and the 31st December 12,443 persons were examined and 48 (113 males and 135 females) were positive. 24 were children under 10 years, 61 between 10 and 20, 159 between 20 and 60 [no subdivision of these decades is given] and 4 over 60 years. The treatment adopted was by antypol and trypanamide. The former was given thus for an adult: First dose 0.5 gm. (three days later 1.0 gm., and thereafter 1 gm. weekly to a total of 7.5 gm.). The trypanamide was given in weekly injections of 2-3 gm. for ten weeks. The results of treatment and any accidents are not dealt with in this report; they are to be detailed in a later report of treatment. The present account includes copies of the various forms for the keeping of records.

Hollins, C. & Lewis-Fanning, E. The Sedimentation Rate in the African Patient with special reference to Trypanosomiasis. *Trans. Roy. Soc. Trop. Med. & Hyg.* 1947 Oct., v 41 No. 2, 217-40 3 figs. (14 refs.)

The normal European blood sedimentation rate is less than 5 mm. in 1 hour but the majority of Africans have readings of between 10 mm. and 15 mm. at one hour and most patients suffering from trypanosomiasis have rates above 20 mm. In determining the sedimentation rate the authors mixed 4 parts of blood with one part of 5 per cent. sodium citrate solution, and they found that when the sedimentation rate is extremely rapid, as in cases of trypanosomiasis, a 10-minute reading is largely a measure of the intensity of the agglutination and a 1 hour reading is an approximation to the packed-cell volume. The cause of the high sedimentation rate of the apparently normal African is obscure. Examination of a group of African troops showed that the majority had plasma albumin to globulin rates of about unity, whereas those of Europeans average 1.7:1. The authors believe that the difference in the sedimentation rates is associated with this difference in the albumin-globulin ratio, and that the clinical significance of the high African sedimentation rate is an indication of diminished resistance to disease.

In trypanosomiasis the increase in the sedimentation corresponds roughly to the clinical severity of the disease, and in some districts with the changes in the cerebrospinal fluid. It may be that as the sedimentation rate rises with the progression of the disease the rate is high by the time the nervous system is affected, or it may be that when the sedimentation rate is high the nervous system becomes susceptible to infection. It is suggested that the sedimentation rate is an expression of the equilibrium between the patient's resistance and the virulence of the trypanosome, variation in the patient's resistance being probably a more potent factor in causing change in the sedimentation rate than is variation in the virulence of the trypanosome. In trypanosomiasis a low sedimentation rate indicates an early infection or a long, standing infection of low virulence; a high sedimentation rate probably carries a poor prognosis as it indicates a relatively low resistance on the part of the patient. Trypanocidal therapy rapidly reduces a high sedimentation rate in trypanosomiasis. Consequently, although not replacing proper clinical and laboratory examinations,

determination of sedimentation rates is a valuable auxiliary measure in assessing treatment and in the diagnosis of cryptic infections. During mass surveys sedimentation rates should be determined in all individuals in whom trypanosomes cannot be found. Patients with a high sedimentation rate may then be given a single injection of antrypol or pentamidine and re-examined a month later. Those showing a pronounced fall in sedimentation rate should be regarded as cases of trypanosomiasis.

The authors quote a large number of observations in support of their views
F Murgatroyd

LAUNOY, L. Essai sur la chimio-prévention, par voie orale, chez le rat, de l'infection expérimentale à *Trypanosoma gambiense* [souche Yaoundé] (Note préliminaire) [Chemoprophylaxis by the Oral Route against the Yaoundé Strain of *T. gambiense* in the Rat] Reprinted from *Ann Pharm Françaises* 1947, Dec, v 5, 599-605

The Yaoundé strain of *T. gambiense* has neurotropic properties in mice and rats [ROUBAUD and PROVOST, this *Bulletin*, 1942, v 39, 234, STÉFANOPOULI and ÉRÉVÉ, *ibid*, 1945, v 42, 258, ROUBAUD, STÉFANOPOULI and DUVOLON, *ibid*, 1946, v 43, 419]. The neurotropic effects are somewhat more pronounced in mice, in which the most striking feature is paralysis of the hind limbs, than in rats, which exhibit somnolence, irritability, tremors, loss of sphincter-control and sometimes paralysis.

The authors have found the incubation period of this strain in rats to average 22-23 days and the total duration of infection to vary widely around a mean of about 65 days. Previous workers with this strain in rats have found that trypanosomes are only occasionally to be seen in the blood, and then only in small numbers, a terminal septicaemia being very infrequent. LAUNOY finds now, however, that two types of infection are of most common occurrence, as follows: (a) Parasites slowly increase to a fairly high count, and there are then several waves of alternate trypanolysis and re-accumulation of parasites, which are frequently present in more or less great number, and can be seen until death for more than a month. They may continue to be scanty or absent up to the time of death. This type of infection is usually more chronic than type (a).

Prophylactic experiments were carried out with "Lomidine", which is the 2, 2'-methylene-bis-hydroxynaphthoate of pentamidine base, administered orally. This preparation is insoluble in water, but is apparently absorbed in the intestinal tract. Doses of 0.15-0.3 gm per 100 gm body weight were given orally, and a heavy suspension of trypanosomes was then inoculated intraperitoneally 1 to 8 days later, in 17 rats, with an equal number of controls. In another experiment the dose was 0.2 gm per 100 gm body weight, but there were only 2 rats, with 1 control, in this particular experiment. All the untreated rats became infected in the usual way, but those treated prophylactically remained free of infection within observation periods which varied up to about 285 days.

PIFANO C., F. MAYER, M., MEDINA, R. & BENAVIDES PINTO H. Primera comprobación de *Trypanosoma rangeli* en el organismo humano por cultivo de sangre periférica. [First Demonstration of *Trypanosoma rangeli* in the Human Body by Cultivation of the Peripheral Blood.] *Archivos Venezolanos de Patol. Trop. y Parasit. Med.* 1948, Jan. v. 1 No. 1: 1-31, 8 figs. (13 refs.) English summary.

Since the discovery by TEJERA in 1920 (this Bulletin 1921 v. 17: 97) of *Trypanosoma rangeli* in the gut of one of the vectors of Chagas's disease *Rhodnius prolixus* from Venezuela, it was suspected that this parasite had a vertebrate host as well. It was subsequently reported, alone or in association with *T. cruzi* from Triatomid bugs of Uruguay, Colombia and Venezuela. The recent finding of *T. rangeli* together with *T. cruzi* in laboratory-bred *R. prolixus* fed on a patient suffering from Chagas's disease seemed to indicate that the first named trypanosome was a human parasite (DIAS and TORREALBA, 1943; this Bulletin 1946 v. 43: 108). Its presence in two other patients from Venezuela was also demonstrated by xenodiagnosis by MEDINA (unpublished) and finally in the present paper the authors record the successful isolation of *T. rangeli* in culture (N-VV medium) of the blood from a girl, aged 12, in Venezuela. The patient was suspected to be suffering from Chagas's disease but cultures revealed only developmental stages of *T. rangeli* corresponding to those found in *Rhodnius*. All attempts to infect various animals (rodent, cat, lizards, fowls) have so far failed.

The greater part of this paper is devoted to a detailed description of the stages of development of *T. rangeli* in culture and in the bug. In the latter the flagellates occur throughout the alimentary tract and are represented by long and short tritrichid forms and by slender trypanosomes measuring on the average 41 μ and 43 μ in length respectively. Similar forms are found in cultures. The flagellates differ from the corresponding forms of *T. cruzi* in the minute size of the kinetoplast and in other structural features which are evident in the numerous figures illustrating the paper. DIAS E. Importancia continental da doença de Chagas. [Importance of Chagas's Disease in South America.] *Brasil-Médico* 1948 June 5 & 12, v. 62, Nos. 23/24: 17-19. (32 refs.)

The author has brought together recent figures showing the prevalence of Chagas's disease and of the vectors of *T. cruzi* in different countries of South America. From a small zone of Bambuí more than 65,000 of the bugs were sent to the Oswaldo Cruz Institute in the space of 4 years and 14,750 from 13 huts. Cardiac lesions are common and serious: they were present in about half the chronic cases in Minas Gerais and in 95 per cent of those there were signs of interference of conduction (all grades) in nearly half blockage of the

right ramus Sudden death from these heart conditions is common The extent of spread of infection is evidenced by the fact that among 144 students of Tucumán, Santiago del Estero and Catamarca, 23.7 per cent were positive by xenodiagnosis and 30 out of 72 gave a positive fixation of complement

In Uruguay many hundreds of acute cases have been reported and TÁLICE stated in 1939 that there were 4,000-5,000 acute cases there every year In Paraguay not many cases have been recorded but they are probably fairly numerous because infected transmitters are common in the rural dwellings In Chile, infection was found in 40 per cent of 9,000 triatomas examined and 31.8 per cent of 1,445 sera of rural inhabitants gave positive complement fixation reactions In Bolivia, 54.3 per cent of 791 vectors examined were infected and 12.6 per cent of 961 xenodiagnostic tests were positive, as were sera of 23 out of 74 examined In Venezuela nearly half (48.8 per cent) of 3,429 specimens of *Rhodnius prolixus* were positive according to MEDINA, DAS in 1945 found 56.3 per cent positive among 2,802, and PIFANO 76.2 per cent of 1,735 examined Other places are mentioned but only in general terms, thus, in Panama "scores of cases and several fatal", in French Guiana "it is well known that infected transmitters are present and also that there are cases of infection", DAVIS and SULLIVAN found 1,909 positive results to complement fixation in Texas [the total examined is not stated]

DE FREITAS, G & DE CASTRO, F T Cultura de *S. cruzi* em meio autoclavavel, isento de células e proteínas precipitáveis (Nota preliminar) [Culture of *Trypanosoma cruzi* in an Autoclaved Medium, free from Cells and Coagulable Proteins] Hospital Rio de Janeiro 1948, May, v 33, No 5, 725-30

The English summary appended to the paper is as follows —

"(1) The authors demonstrate that fresh blood can be substituted by an enzymatic digest of lyophilized blood, in supporting the growth of '*S. cruzi*'

"(2) A new liquid medium (DP-30) for '*S. cruzi*' is presented, free from cells, particles and coagulable proteins and sterilisable by autoclave

"(3) The medium is basically composed of a peptic digest of blood, tryptic peptone and dextrose Full details on the preparation are given in the developed text

"(4) Twenty-five transfers have been obtained until the publication of this note, without any sign of decrease of the multiplication capacity of the organism

"(5) Some preliminary counts revealed 8,000,000 individuals per cc in tubes with 4 cc of medium and inoculated with 25 per cent of a culture With large inocula, (50%) approximately 12,000,000/cc can be obtained in flasks with 100 cc of medium

"(6) The culture can be done in tubes for maintaining the samples or in Erlenmeyer flasks for large scale production"

FLOCH H & CAMMIN R Deux nouveaux cas de maladie de chagas en Guyane française [Two New Cases of Chagas's Disease in French Guiana] Bull Soc Path Exot 1948 v 41 Nos 5/6 347-50

BRUMPT L C Trois cas de maladie de chagas avec présence de cellules de Mott dans le sang [Three Cases of Chagas's Disease with Mott Cells in the Blood] Bull Soc Path Exot 1948 v 41 Nos 5/6 350-53

POUNT, L. La cardiopatía crónica de la enfermedad de Carlos Chagas. [Chronic Cardíopathies in Chagas's Disease.] *Revista Méd. Iguazú*. 1948 June 4 v. 35 No. 23 1075-88. [57 refs.]

The author gives an account of and discusses 73 cases of Chagas's disease from the point of view of the cardiac conditions they were seen in the Medical Faculty of the University of Bahia, Brazil. The diagnosis in each case was made by complement fixation with the Davis antigen or by xenodiagnosis, in many instances by both methods. Examination of the heart was made in 40 of the patients by physical, radiographical and electro-cardiographic means. In 32 (written of as 80 per cent.) there was interference of propagation of the stimulus, auriculo-ventricular or intraventricular and in 23 (57.5 per cent.) disturbance of the start of the stimulus and in 47.5 per cent. (19 cases) alteration of rhythm.

In more detail partial A-V block was found in 8 patients, total in 11. I-V block of the right ramus in 19 none of the left. Primary changes of the ST and T in 25, ventricular extrasystoles in 22, auricular in 4 supraventricular paroxysmal tachycardia in 1.

In an extensive table are shown the clinical manifestations—subjective and objective signs, arterial pressure, the Wassermann, Kahn or Hime reactions—the X-ray findings and the electrocardiogram of each of the 40 patients. (The preparation of this article must have entailed much work and study to which no mere abstract can do justice. Close study of the details is needed by those interested to appreciate the heart lesions of Chagas's disease.)

LEISHMANIASIS

WILNER, P. R. & HARDICKE, T. A. Relapsing Kala-Azar. Report of a Case with Cure effected by Stilbamidine. *New England J. of Med.* 1948 Aug. 1, v. 239 No. 7 50-53, 5 figs. [13 refs.]

"A case of kala-azar is reported. Difficulties in diagnosis were encountered emphasising the varied nature of the disease. The patient relapsed after two courses of neostibosan. Complete cure was obtained with 4.325 gm. of stilbamidine. It is suggested that kala-azar be included in the differential diagnosis of any obscure febrile illness. Stilbamidine may be considered efficacious in relapsing visceral leishmaniasis until better toxic drugs have been proved to be of value.

GIVA, A. & BINAGHI, G. Alterazioni cardio-circolatorie nei bambini affetti da leishmaniosi viscerale. Cardiovascular Changes in Children with Visceral Leishmaniasis. *Chir. Pediatr.* 1947 Sept. v. 24 No. 9 534-47. 3 figs. [27 refs.]

The authors have examined 11 children, their ages ranging between 17 months and 14 years suffering from infantile kala-azar. For each of these they have noted the systolic and diastolic arterial pressure, the venous pressure

the pulse and respiration rates, the red and white cell counts, the haemoglobin and the electrocardiogram. The details recorded differ within fairly wide limits, particularly the blood-cell counts. The red corpuscles ranged between just over 1 million and over 4 millions, and the white corpuscles between 2,800 and 10,200 per cmm. Generally, the arterial pressure [presumably the systolic] was a little below the normal and the pulse tended to be more rapid, owing in large part at least to the anaemia present. The PQ interval was usually increased, and, taken in association with the tachycardia, is to be interpreted as a retardation of the atrio-ventricular conduction. In one only was there respiratory arrhythmia and in none was extrasystole seen. In brief, the electrocardiogram shows no valid evidence of change which can be regarded as characteristic of leishmaniasis, but merely as indicating myocardial affection which may result from a toxic factor or the anaemia present, and the absence of its modification after injection of atropine does away with the hypothesis that the blockage is of a "nervous character".

FEVERS OF THE TYPHUS GROUP

WEYER, F, FRIEDRICH-FREKSA, H & BERGOLD, G. Die Beziehungen der Rickettsien zu Bakterien und Viren [The Relationships of Rickettsiae to Bacteria and Viruses] Reprinted from *Die Naturwissenschaften* 1944, Nov-Dec, Nos 44/52, 361-5, 6 figs [10 refs]

This paper is illustrated by six photographs of *Rickettsia mooseri*, five were taken with the electron microscope at a magnification of 40,000 diameters, and one with dark-background illumination at a magnification of 1,000 diameters. The technique employed is described.

The authors claim that the findings indicate clearly the absence of relationship between rickettsiae and the elementary or polyhedral bodies of viruses. On the other hand rickettsiae resemble bacteria in having a rounded form and a definite internal structure, they multiply by fission, are insoluble in weak solutions of NaOH, and contain a polysaccharide related to that of *Proteus X* strains, as is shown by the Weil-Felix reaction.

GIROUD, P & VARGUES, R. Diminution du nombre de rickettsies virulentes par dessiccation [Reduction caused by Desiccation in the Number of Virulent Rickettsiae] *C R Soc Biol* 1948, Apr, v 142, Nos 7/8, 438-40

Suspensions were made from the lungs of mice heavily infected with epidemic typhus rickettsiae, half of each was kept at -24°C to serve as a control, the rest was desiccated by three different methods (1) Over calcium chloride *in vacuo* at 15°C , (2) Lyophilization by the method of Flosdorff and Mudd, and (3) Lyophilization by the method of McFarlane, in which the suspension is kept at a temperature of -16°C till desiccation is complete.

The virulence of the three products was estimated by Giroud's rabbit intradermal test, four different dilutions of each product were injected into one flank of a rabbit and four corresponding dilutions of the control suspension were injected into the other flank. An arbitrary standard, based on the diameter and thickness of the resultant skin swellings, was adopted. The reduction in virulence of the first product was estimated as being 1,000 to 1, of the second it was 100 to 1, and of the third, 10 to 4.

The three products when inoculated intraperitoneally into guinea-pigs, and when tested for their power of fixing the agglutinins of an immune serum, showed little difference in their activity.

[Doubts may be felt as to whether the extent of the skin reaction constitutes a true index of the number of virulent rickettsia surviving in each product.]

Contribution à l'étude sérologique du typhus exanthématique. [A
Contribution to the Serology of Exanthematic Typhus.] *Arch. Roumaines
Path. Exp. et Microbiol.* 1945-1946-1947 v. 14 No. 1,4 113-35.
[18 refs.]

The authors describe a technique by which they claim to have obtained consistently definite results in a survey of the incidence of Weil-Felix reactions among the inhabitants of various villages of Rumania in which outbreaks of typhus had occurred or were occurring.

The percentage of positive titres between 1:200 and 1:400 was 31.1 in persons who had been attacked within the previous year; it was 10.3 among those who had been in direct contact with infected persons; 8.1 among other persons in the villages, and only 3.7 among the inhabitants of unaffected villages. No higher titres were observed among persons not actually suffering from the disease. Every patient had a titre above 1:400 and the occurrence of titres of 1:1,000 or over was regarded as evidence of the presence of the disease in a village.

Among persons vaccinated with the Weigl or Cox type of vaccine the highest titre observed was 1:250.

GIRLOUD P. & LE GAC P. Parenté sérologique de la fièvre boutonneuse et du typhus épidémique. [The Serological Relationship between Boutonneuse Fever and Epidemic Typhus.] *C. R. Soc. Biol.* 1948 Apr. 142 No. 7, 8 438-8.

Rickettsia-agglutination test against murine and epidemic rickettsiae was carried out on the sera of 11 patients suffering from boutonneuse fever contracted in France. Reactions against epidemic rickettsiae occurred at titres of 1:160 or over in seven patients, and in four of these cases there were also positive reactions though at lower titres against murine rickettsiae.

Weil-Felix tests were carried out on seven of the patients: four reacted with *Proteus OX19* at titres of 1:100 or over; two of these reacted also with *Pr. OX* and one with *Pr. OXA*.

The authors conclude that there is an antigen common to epidemic typhus and boutonneuse fever which could explain certain points that are still obscure in our knowledge of the typhus fevers.

LEY H. L., JR., SMADKE, J. E. & CROCKER, T. T. Administration of Chloromycetin to Normal Human Subjects. *Proc. Soc. Exper. Biol. & Med.* 1948, May v. 68, No. 1 9-12, 2 figs.

Courses of chloromycetin were given by the mouth to three healthy medical men as a preliminary to a trial of the drug on typhus patients.

The levels of the drug in the blood and urine were tested by a modification of a method devised by JOSLYN and GALBRAITH and personally communicated by them to the authors, this is based on the inhibition of the growth of *Shigella sonnei*

Initial doses of 1.0 gm followed by a ten-days' course of 1.0 gm daily in five divided doses were given to two of the volunteers

In a second test initial doses of 2.0 gm followed eight hours later by single doses of 0.5 gm were given. Appreciable amounts of the drug were detected in the blood within 30 minutes of the first dose, excretion was rapid and no ill effects were detected by examination of the blood and urine or by the volunteers themselves

SMADDEL, J. E., LÉON, A. P., LEY, H. L., Jr & VARELA, G. Chloromycetin in the Treatment of Patients with Typhus Fever. *Proc Soc Exper Biol & Med* 1948, May, v 68, No 1, 12-19, 6 figs

Five typhus patients in a hospital in Mexico D F were treated with chloromycetin by mouth under close expert observation. Three of the patients were adults suffering from epidemic typhus and two were children, one of whom had epidemic typhus and the other had murine typhus. The differential diagnosis was based on rickettsia-agglutination and complement-fixation tests, the former of which in four of the five cases and also in three of six untreated cases became positive several days earlier than the latter.

The detailed case reports suggest that the drug may have been beneficial, but the authors are cautious in their conclusions, which are that the drug is relatively safe and that the effects were sufficiently encouraging to justify further tests.

The dosage suggested is an initial dose of 40 mgm per kilo of body weight followed by a total daily dose of 35 mgm per kilo given in divided two-hourly doses till improvement is noticed and then by a maintenance total daily dose of 20 mgm per kilo given in divided amounts every four hours till the 13th or 14th day after the onset

ORTIZ MARIOTTE, C. Vacuna profiláctica contra el tifo. prueba de campo [Prophylactic Anti-Typhus Vaccine, a Field Test]. *Bol Oficina Sanitaria Panamericana* 1948, Apr, v 27, No 4, 330-41. English summary

A field test was carried out in strictly controlled conditions in three rural areas of South Mexico. The vaccine used was of the bivalent, Castañeda type containing four parts of murine rickettsiae and one part of epidemic rickettsiae.

Among 234 vaccinated persons there were 15 attacks of clinical typhus [apparently louse-borne] and among 214 comparable controls there were 18 attacks. The average severity of the attacks in the vaccinated group was considerably less than in the controls, 17 of the control patients had "severe" or "average" attacks whereas only 6 of the vaccinated fell into these grades. Although the difference in severity is regarded as statistically significant the authors regard the figures as too small to justify final conclusions.

The trial was carried out in 1942-1943, and the authors mention that an improved vaccine has given good results among persons specially exposed to the risk of infection since 1945.

SAVOOR, S. R., VAHIA, N. S. & SOMAN, D. W. Typhus in Bombay. Part III. Identification of Strains. *Indian Med Gaz* 1948, Feb, v 83, No 2, 70-74 [15 refs]

Strains identified as *Rickettsia mooseri* were isolated from the blood of five patients in Bombay, by mouse inoculation. With simultaneous guinea pig

inoculation only three of the strains were isolated, and as the spleen and brain of infected mice remained infective to guinea-pigs for at least two months the mouse is regarded as the animal of choice for recovering and maintaining infection.

All the strains were orchitic and in other respects gave reactions regarded as indicating a murine type of infection.

A similar strain was isolated from a pooled suspension of the brains of four rats from a house in which a case of the disease had occurred—pools made from the brains of 19 other rats from this house were not infective.

One of the human strains was transmitted, from guinea-pig to guinea-pig from rat to rat and from mouse to mouse by the bites of *Xenopsylla cheopis*.

One strain was maintained in rats for 20 successive passages.

Each of the three strains tested caused complete cross immunity in guinea-pigs against the other two strains but guinea-pigs convalescent from the infection were still susceptible to the Wilmington strain of murine rickettsiae, though only two of the five guinea-pigs tested developed a acrotal reaction. On the other hand the Wilmington strain caused complete immunity against the Bombay strains, which, therefore were regarded as being of lower virulence.

Complement-fixation tests were not carried out and doubts are expressed on the reliability of this reaction—it is stated that a murine strain similar in every respect to the Bombay strains was isolated from a patient in Mysore whose serum had been tested by TOEPFEL and had been regarded by him as giving a fixation reaction indicating a closer relationship with Rocky Mountain spotted fever than with murine typhus.

[The occurrence of this conflict in evidence makes it all the more desirable to carry out complete serological tests.]

John W. D. Meigs

BALTEANU, I. & CONSTANTINESCU, N. Sur une nouvelle rickettsiose murine [A New Murine Rickettsial Infection.] *Arch. Roumaines Path. Expt. et Microbiol.* 1945-1946-1947 v. 14 Nos. 1-4 136-85 15 figs. & 7 pls (1 coloured) (11 refs.)

In a long paper the authors describe an exhaustive investigation of a murine strain of rickettsia isolated by inoculating guinea-pigs with a pooled suspension of the brains of four rats trapped in Jassy Rumania. One of the rats had a Weil-Felix reaction at a titre of 1-600. The strain was regarded as intermediate between epidemic and murine rickettsiae. It caused an intense febrile and toxic reaction in guinea-pigs but was non-orchitic. In the earlier transfer through guinea-pigs brain substance alone was used as the inoculum and there was a considerable falling off in virulence, but when blood or spleen-suspension was used the virulence at once became greater and it remained constantly high through the rest of the series of 63 transfers. Transfer through a rat also caused an increase in the virulence of the attenuated strain—this had become non-infective to mice but by the 20th passage the brain and spleen of infected mice caused a sharp febrile and orchitic reaction in guinea-pigs.

Rabbits, dogs, and spermophiles were susceptible but cats resisted attempts at infection.

A human volunteer was inoculated subcutaneously with brain substance of the guinea-pig of the 1st passage and developed a febrile attack lasting 1 day, there was a papular rash, and the Weil-Felix reaction was positive in rising titre which reached 1-400 by the end of the attack.

Another volunteer was inoculated with brain and spleen suspension from a guinea-pig of the 42nd passage. He had an insignificant reaction, detected only by the isolation of rickettsiae from the blood. Three other persons inoculated in the same way from guinea-pigs of various passages did not react.

The spermophile, *Citellus citellus*, harboured infection for at least 40 days in its brain and spleen and was regarded as the animal of choice for maintaining the strain. There was no cross-immunity with epidemic-typhus rickettsiae. Many other observations were made but there is no mention of complement-fixation or rickettsia-agglutination tests.

John W D Megaw

LIU, Wei-T'ung, WANG, Pe'i-Jen & CHING-CHANG, Hwei. Typhus-like Fever of *Proteus vulgaris* OXK Type in Northwest China. Report of Six Cases. *Chinese Med J* Shanghai 1948, Mar, v 66, No 3, 130-40 [23 refs]

Six cases are described in which the *Proteus* OXK type of Weil-Felix reaction occurred at titres of 1-160 to 1-640, one of the patients reacted against *Pr* OX19 at a titre of 1-80, all the others were negative with *Pr* OX19 and *Pr* OX2.

In four of the cases complement-fixation tests against epidemic-typhus antigens were carried out, three were negative, but one reacted at a titre of 1-1,024 though his serum did not agglutinate *Pr* OX19 or OX2. Among 353 normal persons in the area only two gave an OXK reaction (at a titre of 1-80), and among 37 typhus patients only three gave OXK reactions, at titres ranging from 1-80 to 1-320.

In view of the above and other considerations the authors conclude that the cases "might represent a disease closely related to, if not identical with tsutsugamushi disease".

Five of the patients were residents of Lanchow, situated on the Yellow River which periodically floods the city and its suburbs.

It is stated that FAUST in 1923 found organisms, which he regarded as resembling *Rickettsia moppo*, in spleen sections from two patients in Wuchang and that he suggested the possible occurrence of tsutsugamushi disease in the lower Yangtse Valley. Apart from this the only previous evidence of the occurrence of the disease in China is said to be the recent finding by WEI of typhus cases of the *Pr* OXK type in Kunming in South-West China.

KELSEY, W M & HARRELL, G T. Management of Tick Typhus (Rocky Mountain Spotted Fever) in Children. *J Amer Med Ass* 1948, Aug 14, v 137, No 16, 1356-60, 3 figs [Refs in footnotes]

The authors point out that tick typhus is now more prevalent in some Eastern States than in the Rocky Mountain area which till recent years was regarded as the only part of the world in which the disease occurred. In 1945 only two cases were reported from Montana, and six from Idaho, whereas 99 were reported from Virginia and 57 from North Carolina. The case-mortality rate in North Carolina during 1944 and 1945 was nearly 32 per cent.

The present paper deals with 27 cases among children, there were seven deaths, but this high mortality rate is attributed to the fact that most of the patients were sent to hospital because their condition was critical.

Only 50 per cent of the patients were known to have been bitten by a tick shortly before the onset. With the Weil-Felix test the highest titres observed were the *Proteus* OX19, though in one patient who died the OX2 and OXK strains gave higher titres. The complement-fixation test was indicative of tick-borne infection though three patients gave reactions against murine rickettsiae, but in each case at a lower titre.

Treatment with hyperimmune rabbit serum was tried in some cases, among the six patients whose treatment was started within three days of the onset there was no death, but two patients treated from the 5th day onwards died, and the mortality in the serum-treated group as a whole was 25 per cent.

The general treatment was supportive the authors believe that several patients were saved who otherwise would have died. A high intake of proteins and vitamins was maintained.

In the discussion one speaker rebuked the authors for using the name tick typhus he said that this name would apply equally to boutonneuse fever which was a different disease. The senior author defended the name on several grounds especially because the name Rocky Mountain spotted fever had misled many practitioners by suggesting that the disease was limited to a geographical region and because the name tick typhus correlates the disease with the vector just as happens with the names louse borne typhus and murine typhus.

CAUSBY O. R. & HUMM H. W. Dispersion of Forest Mosquitoes in Brazil. Preliminary Studies. *Am. J. Trop. Med.* 1948, May v 28 No. 3 469-80 2 figs.

Two experiments with forest mosquitoes were made in the Passos region in Minas Gerais, Brazil from April to June 1947 during an investigation into the rôle of these mosquitoes in the dispersion of yellow fever. The object of the first experiment was to determine whether marked mosquitoes could be recaptured and whether they remained localized or left the point of liberation. 1,870 *Haemagogus spegazzini*, 903 *Aedes leucocelaenus* and 8,752 specimens of other sylvan species were therefore marked and released. During fifteen of the following seventeen days 2,074 (18.3 per cent) mosquitoes were recovered. The percentages of recaptures were of *H. spegazzini* 9%, of *Aedes leucocelaenus* 50.8 and of the other species 18.7. Almost half were taken at the point of release and others in the neighbouring forests. 3 *H. spegazzini*, 10 *Aedes leucocelaenus* and 27 others were found in a forest one kilometre from their base point beyond an intervening open pasture. Most were recovered during the first four days, the last *H. spegazzini* on the fifth day and the last *Aedes leucocelaenus* on the twelfth day.

The second experiment was designed to discover the usual flight range of forest mosquitoes. The above-named species were not available in large numbers but other species were common. Among the released species were *Aedes serratus* (6,598), *Aedes scapularis* (2,879), *Taeniorhynchus chrysotolum* (6,876) and *T. fasciolatus* (6,019). In all 31,689 mosquitoes of sixteen species were used. Recaptures were made on twenty-five days during a thirty-day period 614 at the point of release and 29 in 11 of 28 outlying forests. Species recaptured 800 metres or more from the release point were *Aedes serratus* (16), *Aedes scapularis* (5), *Aedes crumifer* (1), *Psorophora ferox* (4), *Anopheles* sp (2) and *Chagasia fajardo* (1). *Aedes serratus* was recaptured in the greatest distance and over the longest time (25 days), it was also found at the greatest distance (4.7 kilometres). *Aedes scapularis*, an experimental vector of yellow fever, was recovered at a distance of more than 4 kilometres, and 11 days after release.

PAUL, J R, MELNICK, J L & SABIN, A B. Experimental Attempts to transmit *Phlebotomus* (Sandfly, Pappataci) and Dengue Fevers to Chimpanzees. *Proc Soc Exper Biol & Med* 1948 May, v 68, No 1, 193-8, 3 figs [10 refs].

Sandfly fever virus contained in human blood samples from Cairo was inoculated subcutaneously and intracutaneously into six chimpanzees. The

only reactions observed were short attacks of fever and listlessness in the two animals which allowed their temperature to be taken.

The incubation period was five days and the fever lasted about six days in both cases. In one animal the chart shows two humps spaced about four days apart and in the other the fever curve appears to be of the saddle-back type. No conclusion was reached regarding the susceptibility of the animals.

Nine chimpanzees were inoculated with strains of dengue virus contained in serum taken three years earlier from human volunteers and kept in a box containing solid CO₂. The temperature of five animals could be recorded; each of the charts shows a slight rise of temperature between the 5th and 10th day after inoculation, and a second slight rise between the 12th and 15th day. Mouse-neutralization tests showed the complete absence of antibodies before inoculation and the presence of abundant antibodies 54 days after inoculation. There was therefore evidence of the occurrence of an inapparent infection.

MELNICK J. L., CURNICK F. C. & SABIN A. B. Accidental Laboratory Infection with Human Dengue Virus. *Proc. Soc. Exper. Biol. & Med.* 1948 May 68 No. 1 198-200 1 fig

In the course of the experiments described in the previous paper one of the assistants accidentally received a drop of dengue-infected serum in his eye. Seven days later a macular rash was seen on the face and after a further period of two days there was a sudden attack of fever and vomiting. The temperature remained between 101° and 103°F for about six days.

The mouse-neutralization test was negative on the first day of the fever and became progressively more strongly positive in tests made on the 13th, 25th and 45th days after the onset.

PLAGUE

PUBLIC HEALTH REP. Wash. 1948, Aug. 20 v. 63, No. 34 1102-5. Plague Infection reported in the United States in 1947

No naturally acquired human case of plague has been reported in the United States since 1943. A fatal case is now reported in a 12 year old boy living in Alturas, Modoc County, California. It is believed that he was infected near a Ranger Station, 13 miles south-east of Alturas. Wood rats in this area were found to be infected later in the year. Plague infection had previously been reported from Modoc County in 1934, 1935, 1936 and 1942.

It is significant that the last two human cases of plague reported from the U.S. in 1943 and 1942 respectively occurred in Siskiyou County which borders Modoc County to the west.

Gradual extension to the east of infection in wild rodents or their ectoparasites has already been noted (this Bulletin 1948, 45 171). This fact coupled with the occurrence of occasional human plague infections in the U.S. indicates that the disease is still a problem in that country and that unless control is maintained rigorously plague infection can be expected to extend into any city in the western States having a substantial rat population and might well even spread to rodents of the Great Plains, the Mississippi Valley and the eastern States.

During 1947 infection was reported in 13 species of wild rodents or their parasites in six western States, namely Arizona, California, Colorado, Hawaii,

Washington and Texas The pools of ectoparasites in which infection was found by mass inoculation were principally fleas, but infection was found in a pool of lice in one case and a number of pools of fleas also included ticks and lice

A lengthy table sets out in detail the number of pools of ectoparasites and of rodents found to be infected in the counties of the six States concerned on various dates during the year [Infections reported in 1946 are discussed in the abstract quoted above]

AMOEBIASIS AND INTESTINAL PROTOZOAL INFECTIONS

NEAL, R A *Entamoeba histolytica* in Wild Rats caught in London
J Hygiene 1948, Mar, v 46, No 1, 90-93, 1 text fig & 2 figs on 1 pl
[11 refs]

Natural infections of rats with *Entamoeba histolytica* have been reported on several occasions from different parts of the world, but this is the first record of its occurrence in rats of England These spontaneous infections are of some epidemiological importance, since it is conceivable that wild rats might act as reservoir hosts of human amoebiasis The author describes the finding of an amoebic infection in seven out of eleven wild rats caught in a London house, among the inhabitants of which were two Cypriots passing abundant cysts of *E histolytica* in their stools It was also shown that the trap between the sewers and the drainage system of the house in question was absent, thus enabling the rats to gain access to the house From these facts it would seem that the infection was acquired by the rats from cysts of a human strain of *E histolytica* The active forms of the amoeba were identical with *E histolytica*, cysts were scanty and represented by immature forms, but in culture typical quadrinucleate cysts developed Infection in the wild rats was restricted to the caecum, in which no lesions were detected However, when cultures of amoebae isolated from wild rats were inoculated intracaecally into newly-weaned white rats they invaded the caecal wall, producing ulceration The amoebae ingested tissue fragments, bacteria and red blood corpuscles The infection in the experimental animals was successfully treated with emetine hydrochloride administered at a dilution of 0.002 per cent in the diet

The paper is illustrated by figures of the trophic amoebae and their cysts, and by photomicrographs of sections of the caecal lesions

C A Hoare

MILLER, M J & CHOQUETTE, L P E Studies on Amoebiasis in Canada.
Part I The Incidence of Intestinal Protozoal Infections in Two Institutionalized Groups in Canada Canadian J Res Sect E Med Sci
1947, Feb, v 25, No 1, 1-4

In a previous survey of 47 orphanage children in Saskatchewan, the senior author [this Bulletin, 1940, v 37, 113] found *Entamoeba histolytica* in the stools of 23 per cent on a single examination, despite a low local clinical incidence of the disease

In order to pursue this subject in Canada, the present authors studied subjects from two institutions in Montreal, namely (1) an orphanage of 163 boys, aged 8 to 10 and (2) an Old Men's Home, with 151 persons aged 32 to 95 (average 50 to 70 years) Orthodox methods of examinations were employed

In group (1) 153 or 97 per cent of the boys and in group (2) 107 or 71 per cent of the men harboured one or more species of intestinal protozoa. The detailed percentage results were as follows —

| | Boys | Men |
|-----------------------|------|------|
| <i>E. histolytica</i> | 37.0 | 21.5 |
| <i>E. al</i> | 87.0 | 37.0 |
| <i>E. nana</i> | 66.5 | 52.0 |
| <i>I. butchli</i> | 3.5 | 5 |
| <i>G. lamblia</i> | 49.0 | 6.0 |
| <i>C. murina</i> | 7.0 | 0 |

The cysts of *E. histolytica* found were classified into the large and small races as defined by SARANTO *et al.* [this Bulletin 1943 p. 40-53] with the following percentages of each —

| | Boys | Men |
|----------------------|------|------|
| Large race | 26.5 | 8.5 |
| Small race | 17.5 | 13.0 |
| Large and small race | 5.5 | 1.0 |

Despite the limited numbers in the groups examined, the results tend to confirm the previous Saskatchewan findings that intestinal protozoa are common in persons in institutions in Canada. The authors state that the results "add further support to the frequently demonstrated but still largely unrecognized fact that the intensity of *E. histolytica* infections is mainly dependent on the sanitary standards of a people and not related to their geographic locale.

The groups were comparable except in age but the extremes of age tended to make their sanitary levels similar. Almost all the subjects had been born in Quebec.

It will be noted that the incidence, intensity and multiplicity of all the parasites was greatest in the boys. A further point of interest is that *Giardia* was common in the boys and rare in the older men and while *E. al* was commoner than *E. nana* in the former the reverse was true in the latter.

The incidence of the small race of *E. histolytica* was high indeed in the older group, it was commoner than that of the large race. The authors discuss this incidence and suggest that although the small race is generally assumed to be a relatively minor rôle as a cause of amoebiasis, its pathogenic status requires to be determined definitely by further studies, both because of its relative frequency and because of the difficulty of distinguishing it from *Endolimax nana* in fresh smears. [See also this Bulletin 1947 v. 44 pp. 1-4 and 1948 v. 45, 517.]

TERRY, L. L. & BORISCHUK, J. The Importance of the Complement Fixation Test in Acute Hepatitis and Liver Abscess. Southern Med. J. 1948 Aug. v. 41 No. 8 601-70, 915, 1011.

ly diagnosis of acute hepatitis or of amoebic liver abscess difficult. presence is suspected. By the time gross physical signs such as a definitely enlarged liver are well advanced and the

damage extensive From collected reports, OCHSNER and DEBAKEY [this *Bulletin*, 1943, v 40, 915] recorded that in only 474 (11.6 per cent) of 4,091 cases of amoebic liver infection has the presence of a gut infection with *Entamoeba histolytica* been proven. A satisfactory complement-deviation test would therefore be of great value in questionable cases of amoebiasis, especially in those with liver involvement. The difficulty in this test lies in the lack of a potent antigen.

For some years, a group in the Division of Tropical Diseases of the National Institute of Health, U.S.A., has been examining the complement-deviation test for amoebiasis. In conjunction with this study, the Medical Service of the U.S. Marine Hospital, Baltimore, has made clinical applications of the test. The present paper is concerned with these.

Fifteen cases of amoebic hepatitis or liver abscess were thoroughly investigated between 1943 and 1947. The patients were males, aged between 17 and 64 years, of various races and nationalities. According to KLATSKIN's classification [*Ann Intern Med*, 1946, v 25, 601] there were 6 patients with acute and 2 with chronic hepatitis, and 5 with acute and 2 with chronic abscesses. A complement-deviation test was performed on each of these by staff at the N.I.H., who were unaware of the clinical diagnosis. The antigen used was obtained by placing an inoculum of amoebae in a dialysing tube in a coagulated egg-white medium covered with Locke's solution fortified with vitamins. After incubation at 37°C for 144 hours, the contents of the tubes were pooled, merthiolate, 1/1,000, was added, and the mixture was refrigerated at 50°C for 3 days. It was then centrifuged for 15 minutes at 20,000 r.p.m., the supernatant fluid was removed and dialysed in tap water, and then in 3 changes of distilled water. The contents of the dialysing tube were evaporated before a fan to about one-fifth their volume before dialysis, the concentrate was again centrifuged at 20,000 for 15 minutes, and the residue was discarded. The supernatant fluid was again merthiolated after being made isotonic with sodium chloride.

Stool examinations were done on 14 of the 15 cases, and of the 14 only 3 were found to contain *E. histolytica* before treatment. Three more were subsequently found to harbour parasites in the gut. In the case of 2 patients the complement-deviation test was not done until some time after specific treatment had been given, one of these gave a positive test, the other a negative. In the remaining 13 cases the test was performed before treatment, 10 gave consistently positive reactions, 2 gave initially negative (false negative) reactions, but on repetition within a few days the test had become positive, one gave a negative reaction on the only occasion the test was done prior to treatment. It was found that the antigen used in each of these 3 cases where negative readings were obtained was lacking in antigenic potency. All 3 cases at subsequent dates gave positive reactions, although re-examination of the same serum of one of them with a potent antigen continued to give a negative result. There was no record in the hospital of a false positive test. [No mention is made of the number of controls examined.] It has not been determined how long after successful treatment of an amoebic liver abscess a positive complement-deviation test persists. In some cases there is a reversal within 1 to 3 weeks, in one case the test remained positive for 2 years, and the patient was clinically well for a period of at least 3 years.

[In the reviewer's opinion the percentage of proven intestinal infections with *Entamoeba histolytica* in the cases referred to in this paper, and in the literature cited indicates a lack of experience and skill in their detection. As the authors indicate "there has been disagreement among experts as to identification of ameba even when examining the same slide," an observation which reinforces the above comment.]

DRAME E. H. & WARTHIN T. L. Amoebic Abscess of the Liver. Therapeutic Problems in various Types of Late Hepatic Amoebiasis. *New England J. Med.* 1948 July 8, v. 239 No. 45, 9

Six cases of late amoebiasis of the liver are described. None had previously been diagnosed as being infected with *E. histolytica*. The onset was usually acute with signs referable to the liver.

The clinical material is divided into three groups: simple amoebic hepatitis, a large liver abscess remaining localized, and a large abscess which had penetrated through the diaphragm. Only one was classified as diffuse hepatitis and was treated by chemotherapy alone.

Two had abscesses of significant size that had not drained into the pleural or peritoneal cavities. These were treated by chemotherapy and aspiration. After the institution of emetine therapy an incision was made in the abdominal wall to permit, under direct vision, the introduction into the abscess of a large aspirating needle. This aspiration was followed by the instillation of penicillin into the abscess cavity and closure of the abdominal wall without drainage. The two abscesses which had penetrated through the diaphragm were secondarily infected and these were treated by open drainage. In the sixth case the abscess had drained spontaneously into the right pleural cavity and through the bronchial tree. The patient was treated by chemotherapy and aspiration of the empyema fluid by thoracentesis.

All were treated by intramuscular emetine in a single dose of 1 grain daily for eight days and by two subsequent courses, each of six days duration. At the termination of each emetine course viosform was given by the mouth, commencing with 4 grains three times daily increasing to 15 grains three times daily for 10 days. Penicillin was injected intramuscularly in doses from 30,000 to 50,000 units every three hours.

Some evidence was obtained by studies *in vitro* in the fifth case that development of resistance to emetine may take place. Amoebae from this patient grew in concentrations of emetine which were much higher than the control strains tested, indicating drug resistance.

Viosform was found to be satisfactory for eradication of *E. histolytica* *in vitro*.

The onset of symptoms referable to the abscess were often acute and without premonitory symptoms. In the second case the physical signs suggested acute cholecystitis. The white-cell count varied from normal to marked leucocytosis. Examination of the faeces was positive in three out of the six. After spontaneous drainage by hepatobronchial fistula the putum was found to contain trophozoites of *E. histolytica* in two cases, while the exudate from abscess cavities with inadequate drainage contained large numbers of motile trophozoites.

CHOSNIE, R. MARLE, BARNIER, MOLINIER & TABI. Traitement de la dysenterie amibienne par les extraits d'*Heliotropium scaberrimum*. [Treatment of Amoebic Dysentery with Extracts of *Heliotropium*.] *Bull. Acad. Nat. Med.* 1948, v. 132, No. 19, 21, 336-8.

The alkaloid of *Heliotropium scaberrimum* acts specifically on the dysenteric amoebae and cysts. To thirteen patients with acute amoebic dysentery was given the total alkaloids of the plant. In 9 the amoebae disappeared in 4 cases there was improvement. Similar to those 11 of 6 patients with cysts in the stools led to the disappearance of the cysts.

Thirteen other patients with acute amoebic dysentery were treated with carnosine hydrochloride. One of these did not complete the course. Eight

intolerance of the drug, the remainder were cured by the treatment. Conessine hydrobromide appeared to be as efficient, and to be free from toxicity

PIEKARSKI, G Zur Frage der Cystenbildung bei *Dientamoeba fragilis* [Encystation in *Dientamoeba fragilis*] *Ztschr f Hyg u Infektionskr* 1948, Apr 1, v 127, Nos 6/8, 496-500, 7 figs

The author has re-discovered, in the stools of an inmate of an institution, cyst-like structures corresponding to the so-called "Bosman-cysts" previously described by BRUG [this *Bulletin*, 1937, v 34, 514]. While Brug left the question regarding the identity of these bodies open, the present author regards them as cysts of *Dientamoeba fragilis*. Subsequent examinations of stools of 133 other persons revealed in eleven cases the presence of the same structures in association with the amoeboid forms of *Dientamoeba*, while in 32 cases only the amoebae and in 21 only the "cysts" were found.

The cysts are rounded or ovoid, measuring $4-9\mu \times 4-6\mu$. When stained with iron haematoxylin a distinct cyst-wall is seen around the enclosed body, which is detached from the wall and contains two dark-staining granular structures. Though these do not always show the characteristic structure of the nuclei of *Dientamoeba*, their nuclear nature was revealed by Feulgen's reaction. In addition there were a number of "chromidial bodies" [=chromatoids]. The author claims to have seen all transitions from the "vegetative cells" of *Dientamoeba fragilis* to these cyst-like bodies, which left no doubt in his mind that they belonged to the same parasite. The appearance of these cysts is shown in a series of figures. He was unable to undertake any further investigations—by experimental infections and cultivation—on the nature of these cysts.

COSTA, R. S *Dientamoeba fragilis* Jepps y Dobell, 1918 Primeros casos señalados en nuestro país. Consideraciones epidemiológicas [*Dientamoeba fragilis* The First Cases recorded in Cuba] *Rev Kuba Med Trop y Parasit* 1948, June, v 4, No 6, 115-18 [24 refs]

In 1941 the author heard of certain skin diseases associated with, and thought to be due to, intestinal parasites. He, therefore, has looked for these in patients coming for treatment of exudative or desquamating eczema, prurigo, urticaria and other skin affections allergic in nature. Eighty-two patients with these dermatoses have been examined and 52 of them had intestinal protozoal parasites. Among 76 patients whose faeces contained protozoa, 4 of the author's patients and one sent in by another practitioner were passing *Dientamoeba fragilis*. The fifth was a child of 7 years, with enterocolitis whose faeces contained also *Entamoeba coli* and *Giardia intestinalis*. Case 1 was in a man of 41, with eczema of hands, face and neck which had troubled him for about 20 years, he had *D. fragilis*, *E. coli*, *Endolimax nana* and *Chilomastix mesnili*. He was given Enterovioform, 3 tablets daily, to a total of 40 tablets. The symptoms cleared up, but a couple of months later they returned and *D. fragilis* was again found. Case 2 was a man of 27, with generalized eczema and prurigo for $2\frac{1}{2}$ years and had *D. fragilis* in his stools. He, too, was given Enterovioform, improvement was rapid and the cutaneous lesions disappeared. He was not seen again. Case 3, a man of 53 years, with pruritus ani for 5 years, *D. fragilis* was abundant. He was given Carbantren and slight improvement took place. Case 4, a man of 18, with generalized scaly eczema, especially on face and hands, 7 years duration. *D. fragilis* very numerous. He was treated with Carbantren, 3 tablets daily for 10 days, repeated after an interval of 8 days. The skin condition was cured and there had been no return when he was seen again nearly four months later.

FILHO F. S. & CASTRO E. L. Patogenia e quadro clinico da giardíase [Pathogeny and Clinical Picture of Giardiasis.] *Rev. Brasileira M. I.* Rio de Janeiro. 1948, Jan., v 3 No. 1 1-15. [Bibliography] English summary.

After noting the opinions of many authors regarding the question of the pathogenicity or mere simultaneous presence of *G. intestinalis* & whether symptoms accompanying the presence of the protozoan are aetiological or connected, the authors record the facts in 15 patients under their observation. The chief subjective complaints were of epigastric pain, nausea, especially in the morning, pyrosis, dyspepsia, bitter taste in the mouth, diarrhoea alternating with constipation, flatulence and headache—symptoms somewhat vague and indeterminate. They believe that the presence of the parasite in the gall-bladder or bile causes spasm of the sphincter and stasis of the bile and some degree of inflammation of the bladder wall. They conclude therefore that *G. intestinalis* has a definite pathogenic action even though a mild one. Treatment by atabrin 0.1 gm. thrice daily for 5 days, proved quite satisfactory.

HERRLICH A. & LIEBMAN H. Die menschliche Coccidiose. (Weiterer Beitrag zur Kenntnis der menschlichen Coccidien.) [Human Coccidiosis. (Further Contribution to the Knowledge of Human Coccidia).] *Ztschr. f. Hyg. u. i. f. Infektionskr.* 1944 Nov 12, v 128 No. 1/2, 23-38 6 figs.

This is a continuation of the authors' previous work on human coccidiosis [this *Bulletin* 1944 v 41 782]. In the present paper they report the results of an experimental study, the main objects of which were to determine the clinical manifestations of the infection and the host-specificity of *Isospora belli*.

An exceptionally heavy infection in a patient (about 10 oocysts per microscopic field in faecal smears) enabled them to carry out experimental infections in man and lower animals. The oocysts were allowed to mature in an incubator at 37°C., after which (30 hours later) they were diluted in water and introduced into the stomach of volunteers by means of a catheter each receiving about 20 cc. of the suspension containing about 100,000 oocysts. The total number of volunteers was ten, 5 of whom were inoculated with the suspension, 2 with centrifuged oocysts and 1 with immature oocysts while 3 others, serving as controls, received 20 cc. of the filtrate from the infective material. The persons to whom ripe oocysts were given started passing immature oocysts in the stools between the 9th and 16th days after infection, their discharge ending after 21 days but those who received centrifuged or immature oocysts failed to acquire an infection. It was thus confirmed that *I. belli* undergoes a definite cycle of development in the human intestine. The infection was produced in the stools. Human coccidiosis is therefore a self-limited disease. Attempts to infect young kittens, pups, mice, guinea-pigs and rabbits were unsuccessful. It is concluded that *I. belli* cannot be regarded as a variant of the common group of *Isospora* of cats and dogs but is a parasite specific to man, though the existence of some unknown animal reservoir cannot be excluded.

YAWS

APTED, I., HARDING, R D & GOSDEN, M A Clinical and Serological Follow-up of Yaws Cases treated by Acetylarsan and Bismuth Sodium Potassium Tartrate *Trans Roy Soc Trop Med & Hyg* 1948, July, v 42, No 1, 55-64

This paper reports observations in eastern Sierra Leone on the cure rates following administration of acetylarsan and bismuth sodium potassium tartrate (BSPT) alone and in combination in two areas about 70 miles apart

In the first area observations were made at the same intervals after treatment with one or both of the drugs, in those patients who showed the worst yaws lesions in a community which had enjoyed facilities for treatment for some years Kahn and modified Ide tests were used, but the latter were found unsatisfactory in following the results of treatment The patients treated were suffering from secondary yaws, predominantly non-infectious plantar lesions

After 6 doses of acetylarsan 4 cc [0.94 gm diethylamine acetarsol], 61 per cent of cases had no lesions and the serum from 50 per cent gave weak (15) doubtful (15) or negative (21) Kahn reactions After 3 doses of acetylarsan 3 cc and 4 doses of BSPT 3 grains [0.18 gm] 49 per cent had no lesions and only 21 per cent had weak (4), doubtful (11) or negative (7) Kahn reactions After 6 doses of BSPT 4 grains [0.25 gm] no lesions were found in 32 per cent and 9 per cent had infectious relapses and the Kahn results were weak (2), doubtful (4) or negative (7) in only 13 per cent All observations were made 6-7 months after treatment, injections were given at intervals of one week and the numbers of patients in individual groups ranged from 28 to 120 Sera from 37 of these cases were examined 12 months after treatment, when only 2 were weak or doubtful and 5 negative, the rest were positive Six months previously the same patients had shown 11 weak and 5 negative Thus it was seen that although acetylarsan was moderately effective, the particular BSPT preparation used was of limited value either alone or with acetylarsan The marked seasonal variations in incidence of yaws lesions complicated the full assessment of therapeutic effect

In the second area observations were made at varying intervals after standard courses of acetylarsan and BSPT together All patients with definite signs of yaws were treated from a community where previously treatment was not so readily available Tertiary yaws cases were omitted from this study Clinical examinations were made at intervals of 6, 12 and 24 months and Kahn tests were carried out at 6, 18 and 30 months The doses of acetylarsan were reduced from 5 cc [1.18 gm diethylamine acetarsol] to 4 cc [0.94 gm] and later 3 cc [0.71 gm] because of toxic reactions, and the dosage of BSPT was 3 or 4 grains [0.18 or 0.25 gm] Both drugs were given on the same day, intramuscularly, and repeated at intervals of 5 days, usually 4 pairs of injections were given

The passage of time made little difference in the clinical or serological findings Of patients with infectious yaws 70, 64 and 76 per cent had no lesions after 6, 12 and 24 months, and 52, 58 and 71 per cent had weak, doubtful or negative Kahn reactions after 6, 18 and 30 months Of patients with non-infectious yaws, 58, 34 and 45 per cent had no lesions and 69, 72 and 69 per cent had weak or negative Kahn tests after the same time intervals The numbers in the groups ranged from 27 to 154, larger doses of drugs had been received by patients followed for the longer times

The authors stress the importance of frequently repeated observation in assessing the clinical relapse rate They conclude that acetylarsan in the doses used will banish the more marked signs of yaws for at least 2½ years and will

perhaps permanently cure one-third of cases (secondary) and that it will render most of the remainder quiescent for an indefinite though prolonged period. In later work they have replaced BSPT by bismuth salicylate in oil, with striking improvement in immediate results. Further data on this are to be published later.

(This paper is the result of much field work and analysis. The reviewer feels that fuller knowledge of secondary and tertiary plantar and palmar jaw lesions, at present non-existent will remove the necessity of using such unsatisfactory terms as "active" "inactive" "infectious" and "non-infectious" each of which comprised a group. Lesions with no certainty that the "inactive" and "non-infectious" groups do not include both secondary and tertiary lesions. Since the publication of this paper HARDING has found that the bismuth content of the BSPT used was only about 4.5 per cent, while that of bismuth salicylate (B.P.) is about 60 per cent.)

LEPROSY

VIRIMA BRAGA, R. Contribuição ao estudo da lepra no meio industrial do Distrito Federal. [Leprosy in Industry in the Federal District (Brazil).] *Rev. Brasileira Med.* Rio de Janeiro. 1948 Apr. v. 5 No. 4 256-60 6 graphs.

During the nine-year period, 1 August 1938-31 July 1947 among 66,64 patients examined at the Industrial Institut 3,008 were suffering from skin diseases and 231 from leprosy i.e. 7 per cent. of the total examined were skin affections and 0.35 per cent. were leprosy. The numbers varied considerably from year to year 20 only in 1941 39 (a peak number) in 1944. Of the total, 93 were suffering with the mixed type 93 with the neural and 40 with the lepromatous type. By far the greater proportion were males but this has little significance as male employees far exceed the females. The majority were between 20 and 40 years of age and the figure was higher in the third decade than in the fourth. As regards trades most of the cases were among tailors bakers and seamstresses [infection from clothes?]. Those engaged in these occupations should be repeatedly and periodically examined.

VALLÉ, S. Diagnóstico precoce da lepra. Parte I II & III [Early Diagnosis of Leprosy]. *Rev. Brasileira Med.* Rio de Janeiro 1948 Apr., May & June v. 5, Nos. 4, 5 & 6, 283-95 377-87 444-54 39 figs. (11 coloured) [Bibliography].

This article contains a good general account of leprosy in its various aspects. It is not easy to see, however why the title is "early diagnosis" for later stages of the disease are included short of actual mutilation. The following indications of the disease are each discussed in turn: the anaesthesia and its usual distribution, the neuritis and neuralgias, the wasting of muscles, particularly those served by the median, the external popliteal, the facial and the supraorbital nerves. The ocular lesions are fully described, with excellent reproductions in colour next the affection of the nasal mucosa and clinical tests, the histamine and pilocarpine tests and the diagnostic differences between lepra and syringomyelia, examination for the bacteria, the Muscular action, the chief features of the lepromatous the tuberculoid and the non-characteristic form and

ending with remarks on other forms of localized anaesthesia, maculae, and nodule formations, carcinoma, sarcoma, sarcoid, yaws and others

DA VEIGA, S As lesões osteo-articulares da lepra através das imagens radiográficas [Bone and Joint Lesions in Leprosy, with Radiographic Illustrations] *An Inst Med Trop* Lisbon 1947, Dec, v 4, 149-60, 24 figs on 12 pls English summary

The author took 400 radiograms of the hands and feet of 100 leprosy patients in the Central Leprosarium of Goa Fifty-eight were males, 42 were females, between the ages of 12 and 67 years, the numbers in successive decades being 5, 17, 27, 28, 17 and 6 The duration of the disease ranged up to 5 years in 23 patients, 6-10 years in 37, 11-15 years in 13, 16-20 years in 10, 21-28 years in 9 in the remaining 8 the duration was not known

The author divides his patients into 5 groups (i) Those with cutaneous lesions only (7 in number), (ii) with marked cutaneous and slight nerve manifestations (18), (iii) purely nerve cases (42), (iv) with marked nerve and slight skin affection (11), (v) with nerve and cutaneous lesions about equal (22) The diagnosis had to be made between leprosy on the one hand and, on the other, tuberculous or syphilitic osteitis, sclerodactylia, scleroderma, Besnier-Boeck disease, syringomyelia and tabes

The pathological process was chiefly destructive, rarefying osteitis and osteoporosis, with cyst-like formation and more extensive destruction resulting in mutilation Some of these, in particular the osteoporotic changes, would seem to be due primarily to vascular disturbance, whereas those changes involving the joints as well as the bones result from leprotic nerve involvement Hence the osteo-articular lesions are most common in those with the nervous form of the disease and were more marked in the feet than in the hands [The article is illustrated with 24 excellent radiographic reproductions and more can be learnt from a study of these than from any abstract or even pages of letterpress]

MONTEL M L R Deux cas de réactions lépreuses aiguës, fébriles traités respectivement par le bleu de méthylène et l'émétique [Two Cases of Acute Febrile Leprosy Reaction treated respectively with Methylene Blue and Tartar Emetic] *Bull Soc Path Exot* 1948 v 41 Nos 5/6, 312-18 2 charts

FONTL, J & ROSSELL C S C Contribuição ao tratamento da lepra pelo 'promin' Controle dos doentes pela pesquisa do bacilo no sangue [Treatment of Leprosy by Promin Control of Cases by Examination for Bacillaemia] *Brasil-Médico* 1948, Apr 17 & 24, v 62, Nos 16-17, 170-76

The authors treated 8 cases of the lepromatous type of leprosy with Promin All had bacilli in the nasal mucus, in specimens from the skin scarifications and in samples of blood Three methods of blood examination were used, that of Crow, of Rivas and of Gomes de Faria, all cases were positive with the last but not all with the other two Of the 8 patients 7 were males, 1 was a female, their ages ranged from 19 to 45 years and the number of injections given was up to 240, in series of 10-18 injections, the average dose about 4 gm (3.8-4.4) Slight exacerbation of symptoms succeeded the beginning of treatment—focal reactions or nodular erythema—but this disappeared with further treatment The nodules softened, nasal obstruction and coryza disappeared, the erythematous patches were clearing and weight increased Nervous symptoms

remained unchanged. In other respects there was no change. Bacteria were still present in the nasal mucus, the skin, the blood, and the Mitsuda's action (negative in all but one) remained the same. The bacteria, however, though present, were more fragmented and less acid fast. Details are given of each of the eight treated.

PICCARDI G. & RADARLI G. Sulla ricerca sul comportamento dei composti di Molibdeno negli organi leprosi. [On the Behaviour of Molybdenum Compounds in Leprous Tissues.] *Spectrochimica Acta* 1948, v. 3 No. 2, 233-4. 1 fig.

That methylene blue injected into the living body stains the tissues and organs attacked by *Mycobacterium leprae* and electively the bacteria themselves is well known. It is also known that ammonium molybdate and methylene blue in solution when added together produce a dark blue solid. Hence there arose the idea of localizing, as it were, the molybdate in the affected tissues by means

of the methylene blue and obtaining thereby a more energetic action of the drug. The following researches were carried out. (1) A leprosy nodule stained with methylene blue in a young patient, was extirpated and divided into two. One part was immersed for a certain time (not stated) in a solution of Am. molybdate, the other not. When subsequently immersed in 95 per cent. alcohol the latter was rapidly decolorized, the former retained the colour, confirming the strong action of the molybdenum. (2) The patient who had many lepromata, some of which were stained with methylene blue was given a series of intravenous injections of 1 per cent. Am. molybdate. Five days after the course ended, two nodules were extirpated, one which had been stained, and one which had not and was of the normal red colour. The nodules after treatment with fuming nitric acid gave place to an oily residue. Examined spectroscopically in the UV area, the lines of molybdenum were plain in both the nodules and to about the same degree in both. (3) In order to demonstrate the fixation of molybdenum in the nodule stained with the methylene blue 5 months after the course

of treatment two more nodules, one blue and one unstained, were extirpated from the same patient and the same procedure carried out. No traces of molybdenum could be found on spectroscopic examination. It had been completely eliminated, indicating that the methylene blue had not the effect of fixing the molybdenum.

HELMINTHIASIS

DE MEIRA M. T. V. & GUEIRA J. F. P. & SIMÕES T. S. Contribuição para o estudo do parasitismo intestinal na Ilha do Al. Boa Vista e S. Nicolau (Cabo Verde). *Intestinal Parasitism in the Islands of Sal, Boa Vista, and S. Nicolau (Cape Verde)*. *J. J. Med. Trop. Lisbon* 1947 Dec. v. 4 239-54. English summary (10 lines).

This study of more than local interest bears witness to inter-communication between the islands of the archipelago, and the desire to be an accurate and established

on the island of Sal] There is no statement of the population of these islands and the numbers examined—by the Willis technique—were small, and this fact should be borne in mind in interpreting the findings

In S Nicolau, 117 individuals were examined from 24 localities [in 9 of these only one was examined] and 92 (78.6 per cent) were passing hookworm ova, and 87 of these other ova also, 44 of them *Ascaris* and *Trichuris*. Blood examination revealed but little anaemia, whether the patients had hookworm alone, or with other helminths, or the latter without hookworms. The average number of red cells was $3\frac{1}{2}$ to $3\frac{1}{2}$ million per cmm (in those without parasites 3,630,000), haemoglobin about 50 per cent (in the non-parasitized 67.7 per cent), eosinophiles ranged up to 29 per cent, with an average of 8.2 in those with ankylostomes only, 11.4 in those with other helminthic infestations also, an average of 9 in those with helminths other than ankylostome. Those without any intestinal parasites had an eosinophilia of 7–11 per cent. average 10 [no reason is offered in explanation of this]. Of 125 who had never left the island 94 were infested (75.2 per cent) most (59) with *Ascaris*, next (17), with *Trichuris*.

Specimens of blood were examined also for filariasis, 100 were taken in the daytime and 84 between 9 p.m. and midnight. Embryos of *Acanthocheilonema perstans* were seen in 5 of each (day or night specimens) and in four cases in both.

In the island of Sal 278 individuals were examined for intestinal infestations and 83 (30 per cent) were positive. 19 showed *Ascaris* ova, 10 *Trichuris*, there was none with hookworms, 36 showed *Entamoeba histolytica* and 15 *Giardia intestinalis*.

In Boa Vista, only 85 were examined, 28 were positive, 10 with *Ascaris*, 11 with *E. histolytica*, 7 with *G. intestinalis*, again here ankylostomes were not found. H Harold Scott

TALAAAT, S. M. Renal Concentration Test in Urinary Schistosomiasis and the Effect of Tartar-Emetic on It. J Roy Egyptian Med Ass 1948, June, v 31, No 6 481-6

The ability to concentrate the urine is usually the first function to fail in renal disease. The "posterior pituitary test" for this consists of the administration of 10 units of posterior pituitary extract subcutaneously, after the patient has emptied his bladder and a record of the blood pressure at 5, 10, 15 and 30 minutes, and of the specific gravity of the urine at hourly intervals for 3 hours, after the injection 1,020 being taken as normal.

Of 15 apparently normal individuals only one failed to concentrate urine to an S.G. of 1020. Of 24 cases of pure urinary schistosomiasis (i.e. abnormality confined to the urinary tract), examined both before and after treatment with tartar emetic, 4 failed to concentrate the urine adequately. Tartar emetic treatment it is considered, did not impair the kidney concentration power, indeed in one case the power of concentration after treatment was found adequate where previously it had been deficient. Kidney function is impaired in urinary schistosomiasis, the incidence being thrice that found in controls by the posterior pituitary test [The data supplied in the text and the tables are unconvincing]. A R D Adams

BLAIR D. M. & ROSS W. F. Observations on the Use of Cercarial Antigen in the Diagnosis of Schistosomiasis. *Ann. Trop. Med. & Parasit.* 1948 Apr. v. 4^o No. 1 48-51 1 graph.

The authors describe two methods of making antigens from cercariae for the diagnosis of schistosomiasis. OLIVER GONZÁLEZ and PRATT (this *Bulletin* 1948 v. 43 343) and HATTIX and MOST *ibid.* 1947 44 440 made an antigen from cercariae shed by snails infected with *Schistosoma mansoni*. The cercariae were stored as a dried powder after having been centrifuged down. The liquid antigen was made from this powder by a 1:5000 dilution with 0.5 per cent. carbol-valine. ALVÁS and BLAIR (this *Bulletin* 1948, v. 43, 344 1947 v. 41 828 827) made another antigen from mammalian cercariae presumed to be those of *S. haematobium* fed by naturally infected *Physopus fuscus*. Water from a pond in which the snails were kept was poured through filter paper to trap the cercariae, a rough estimate of the number of cercariae (usually 1,000 to 15,000) trapped on each filter paper being made. The antigen was stored on these filter papers. Liquid antigen was made by macerating the filter paper in 1 per cent. carbol-valine for 48 hours. 1 cc. of carbol-valine being allowed per 2,000 cercariae the fluid being finally expressed and diluted with an equal part of normal saline. The final concentration of antigen works out at the products of 1,000 cercariae per cc. The dose given for each skin test is "about 0.03 c.c.m. which equals the products of 33 cercariae."

CRAWSTON has objected that when "wild" snails are used the exact species of the cercariae is not known. The present authors do not claim that all the cercariae used were those of *S. haematobium* and maintain that no claim has ever been made that antigens made from cercariae are species-specific. Oliver González and Pratt (*loc. cit.*) used antigen from *S. mansoni* to diagnose infection with *S. japonica*. They recommended that the initial weal produced should have a diameter of 4 mm. and consider as positive a weal the diameter of which has doubled to over 8 mm.

Discussing this question, the present authors give a table showing the diameters of weals shown by 39 positive reactors and 36 negative patients at intervals of 5 minutes up to 25 minutes after the injections. The positive group consisted of 1 European, 17 European children and 21 African school children. 22 of these were infected with *S. haematobium*, 3 with *S. mansoni*, 6 with both these species and 8 were passing no eggs. The negative group consisted of 7 Europeans, 1 adult African and 33 African school children. In each of the subjects a control weal was produced with carbol-valine.

The table shows that the antigen weals increased in size in all the positive reactors in comparison with the control weals up to a maximum reached in 15 to 20 minutes after the injections. In the negative group the antigen and control weals showed little or no increase in size. The authors emphasize that the optimum time for measuring the weals is 15 minutes after the injection. Only a few of their subjects showed doubtful reactions. Weals whose diameters increased only to one and three quarters or twice the size of the initial weal. The authors used confetti paper discs with a diameter of 8 mm. and a scale to measurement and a series of cine photographs of the development of the weals of one subject was projected on to squared paper so that the sizes of the weal could be measured and expressed in the graph reproduced in their paper.

Comparison of weals produced by stocks of 5 old antigen, of which the 2 oldest were made in 1933 and 1943 the other being about a year old, showed no significant difference in the reactions produced by these different antigens. The authors advocate the use of control injections for individual diagnosis, especially in Europeans, but they consider that controls are not necessary when

Africans are being tested in mass, because skin allergy is believed to be rare in African subjects, if it occurs at all

G Lapage

MARTINEZ-VILLAFANE, H & LANG, A A The Treatment of Schistosomiasis *Mansoni* with Neostibosan Preliminary Report *Bol Asoc Med de Puerto Rico* 1948, June, v 40, No 6, 128-30

The authors treated 25 adult males suffering from *Schistosoma mansoni* infections with Neostibosan. The drug was given intravenously daily for three days (50, 100 and 200 mgm respectively) and then in doses of 300 mgm on alternate days to a total of 8.45 gm. In only one case was the treatment discontinued because of untoward reaction (a total of 4.25 gm had been given). Reactions in two other cases were controlled by the antihistaminic drug Pyribenzamine.

Immediately after treatment, 7 patients showed "live" ova either in stools or rectal biopsy, 10 showed dead eggs in the biopsy, but none in the stools and 8 had no ova showing in either.

In follow-up studies of 13 cases from one to seven months after treatment, 9 showed positive stools within five months but the follow-up is not yet complete. The author believes that the number of failures will be found to be higher and concludes that Neostibosan has not sufficient parasitotropic effects to warrant its use in the treatment of *S. mansoni* infections.

In a discussion, RODRIGUEZ-MOLINA briefly reviews the therapeutics of schistosomiasis. He emphasizes that in evaluating the results of therapy, false negative stool results may be found in the first month after treatment, probably because of "a temporary inhibitory action on the ovipositing females" on the part of the drug. Stool examination should therefore not be made until a month has passed.

H J O'D Burke-Gaffney

BLAIR, D M Schistosomiasis in Southern Rhodesia. Public Health Aspects *South African Med J* 1948, July 24, v 22, No 14, 462-7 [12 refs]

In Southern Rhodesia schistosomiasis has been reported since 1914, and since then there has been abundant proof that infection is widespread in the country. Both *Schistosoma haematobium* and *S. mansoni* are found, and since 1931 the urinary infection rate has been 2.4-4.9 per cent for Europeans, 18.5-26.7 per cent for Africans, the rates for intestinal infections were 2.1-3.8 and 10-15.6 per cent for Europeans and Africans respectively. The African figures relate to hospital patients, and to that extent are selected. Blair admits that it is not known if the incidence of schistosomiasis is actually increasing, or whether increased awareness is leading to increasing investigation, but his own impression is that there is an increase of schistosomiasis in all sections of the community, and that it is serious. Although it is difficult to assess the importance of the disease as an ultimate cause of mortality, there is little doubt that it causes much illness, and it is regarded as one of the two major problems of public health, the other being malaria. Study of schistosomiasis has been pushed on, in spite of the war.

Attack may be made on the worm, or the snail, at various stages. In the human host treatment can be given which is reasonably effective, the intensive course instituted by ALVES and the author is now well known. In field work diagnosis presents difficulty, and the author shows that many cases may be missed if reliance is placed on a single microscopic examination of urine or faeces. There has recently been an increasing tendency to perform diagnostic cystoscopy, or to take biopsy specimens from the rectum, but even these methods will not reveal all cases, and for diagnosis on a large scale they are not

practicable. Blair describes the antigen for skin testing prepared from cercariae and used on a large scale by Alves and himself [see this *Bulletin* 1947 v 44 826]. The specificity of the test seems to be good and the results have shown that 50-60 per cent. of the African population are positive. In one half of these eggs are found in the excreta. The preparation used for intensive one-day treatment is sodium antimony tartrate and the author has no doubt that it is better to use this than the potassium salt.

Prevention of contamination of streams is of course difficult and little progress has been made, but the attack on the snails is now perfectly feasible. The author uses an empirical dose of 15-20 parts of copper sulphate per million, sprayed in strong solution or broadcast as a powder or dissolved from a sack dragged through the water. Much remains to be learned about the best conditions for treating water and about the snails themselves. The rival claims of fish culture and snail destruction may need to be balanced but in Egypt copper sulphate is used up to 50 p.p.m. without detriment to fish. Naturalistic methods of controlling snails have been suggested but cannot be relied upon.

Irrigation works and water storage dams should be planned from the beginning, with schistosomiasis in mind: the tendency to disregard it until a large snail population is established and human cases have occurred is obviously bad and a proper scheme of water management should be instituted at the outset.

Blair makes the point that *Planorbis pfeifferi* has a restricted and selective distribution yet *S. mansoni* cases are much more generally distributed. *Bulinus tropicus* the intermediate host of *S. haematobium* in Egypt, has never been found infected in Southern Rhodesia. [BAYLES (this *Bulletin* 1947, v 29 408) gives *B. trispinus* as a host of *S. mansoni* and *B. trispinus* (synonym *confluentis dybowskii* (SINUI)) as a host of *S. haematobium*.] Such matters need and are receiving attention.

Cercariae are killed by modern methods of water purification but can penetrate filter and withstand a dose of chlorine which kills bacteria: moreover they can live 100 hours in winter so that storage of water for 48 hours is not the safety measure it was once thought to be. Protection of water is partly a matter of construction of wells and abandonment of the use of streams and dams for domestic supplies or for bathing. But of course this is extremely difficult.

[This is a succinct and readable account of the measures taken to control schistosomiasis in Southern Rhodesia. For other papers by ALVES and BLAIR see this *Bulletin* 1948 v 43 344-752 1947 v 44 826 827 829.]

Charles H. Brock

ABBOTT R. T. *Handbook of Medically Important Mollusks of the Orient and the Western Pacific. Bull. of Zool. Compar. & Zool. Harvard Univ.* 1948 Apr. 100 No. 3 745 328 14 text figs. & 3 pls. 20 cols.]

Relatively few molluscs act as intermediate hosts for trematodes parasitizing man and all those of medical importance belong to the fresh-water Gastropoda. Nevertheless, very parasitologist interested in trematode infections, but lacking the specialized training of a malacologist has performed difficulty when working in the tropics in identifying the comparatively few medically important species occurring in this group and has usually had to rely on sending home his specimens for identification by the expert.

LE TUCKER Abbott handled & written with the praiseworthy object of allowing the field worker in the Orient to identify his snail on the spot. Indeed the book does much of this also when returned from the field for the benefit of

Helminthiasis

Vol 45, No 12]

identification recommended is based on the study of the external characteristics of the living snail as well as on the differentiation of shell characters and, when necessary, a study of the teeth in the radula.

In so brief a handbook—there are only about 100 pages—and one intended for the use of the medical parasitologist, emphasis is, of course, placed on those species which have been implicated as carriers of human disease, but harmless species likely to be confused with their dangerous relatives are carefully described.

Having dealt with the gross anatomy, the shell, and the radula in sufficient detail to enable the tyro to recognize the anatomical landmarks necessary for the identification of species, the author then lists the molluscan carriers of the trematode diseases of man.

The next and most extensive section of the book, consisting of 52 pages, is devoted to a systematic account of the medically important Gastropoda, although, as already noted, it includes brief accounts of species likely to be confused with known vectors. In connexion with the recognition of the molluscan carriers of *S japonicum*, the author writes "In examining dozens of genera and hundreds of species of Pacific and Asiatic fresh-water mollusks over a period of eight months in the field, it was found that all snails capable of carrying *Schistosoma japonicum* cercariae possess these characters: 'Animal with and that no other species of mollusks possess the following animal characters: two slender gray tentacles with a color-streak or "eyebrow" of bright yellow, closely-packed granules embedded in the skin just above the tiny black eyes." It would be interesting to know whether a similar grouping of molluscs susceptible to infection with *S haematobium* and *S mansoni* can be shown to exist in other parts of the world. Although this section of the book is entitled a systematic account, it contains much valuable information concerning the ecology, habits, and distribution of the more important species.

The hosts of *S japonicum* are given as follows —

- Oncomelania quadrasi* Moellendorff
- Oncomelania formosana* Pilsbry and Hirase
- Oncomelania nosophora* Robson
- Oncomelania nosophora slateri* Bartsch
- Oncomelania hupensis* Gredler

The last seventeen pages of the book are devoted to (a) a brief account of the poison cone shells, (b) the technique of collecting and handling infected snails, (c) methods of rearing *Oncomelania* in the laboratory, (d) the control of the intermediate snail host, and, finally, two appendices, the first of which deals with a generic discussion of *Schistosomophora*, *Katayama* and *Oncomelania*, and the second with the revision of the molluscan names appearing in textbooks on parasitology.

This book will form an essential part of the equipment of all workers who are interested in trematode infections of man in the Orient and Western Pacific, and it is to be hoped that its publication will encourage the production of a similar handbook intended for the use of workers in Africa.

R M Gordon

ABBOTT, R T A Potential Snail Host of Oriental Schistosomiasis in North America (*Pomatiopsis lapidaria*) Proc U S Nat Museum Wash 1948, v 98 No 3222, 57-68, 14 figs (12 on 2 pls) [14 refs]

STUNKARD [this Bulletin, 1947, v 44, 432] tested certain North American snails for capacity to act as intermediate hosts of the schistosomes of man, and obtained some evidence that *Pomatiopsis lapidaria* is capable of acting as intermediate host of *Schistosoma japonicum* up to the sporocyst stage [In the

abstract of Stunkard's paper referred to above it is wrongly stated that the experiment was conducted with *S. mansoni*.)

The author describes this snail in detail, and shows on a map the 170 places in the United States from which it has been reported. There are few differences in morphology between the genera *Pomatiospis* and *Oncomelania* and the fact that *P. lapidaria* is a host of *Paragonimus kellicotti* in North America and *O. moroskovi* a host of *P. westermani* in China (CHAN Nat. Med. J. China, 1941 v 27 550) may indicate that the two snails have a similar physiological constitution.

BRACKEN M. M., BAILEY W. R. Jr & THOMAS, H. M., Jr The Lesions of Schistosomiasis Japonica. *Amer J Path.* 1948, May v 54 No. 3 811-23 8 figs. on 3 pls. [18 refs.]

The clinical picture of acute *Schistosoma japonicum* infection among American troops in the Philippines has been widely described—a description of the lesions in man during the acute stage is largely lacking. Death is unusual in the acute stage of the disease but material was available from autopsies performed overseas on three American soldiers suffering from early eastern schistosomiasis. Biopsy specimens from acute lesions in the rectum, liver and skin of other patients were also available and there was material from cerebral lesions in Army personnel returning to the U.S.A. Specimens from older lesions were obtained from three Filipinos who died of gun-shot wounds.

The histological changes of schistosomiasis in man resemble those seen in experimental infections of small animals. The lesions run a fairly uniform course varying slightly from organ to organ. The presence of an ovum at first causes an extensive cellular reaction, eosinophils predominating. Necrosis may occur in a wide zone around the ovum. Epithelioid cells appear and multinucleate giant cells envelop the ovum—these are followed by lymphocytes and plasma cells. Fibroblastic and capillary proliferation develop in the periphery of the lesion which ultimately fibroses—the ovum becomes shrunken and calcifies in a dense fibrous tissue mass with moderate lymphocytic infiltration.

ESKOLA, O. On the Amount of Urobilin excreted in Urine and Faeces in Pernicious Tape-Worm Anaemia and its relation to the Reticulocyte Crisis. *Ann. Med. Intern. Fennic.* 1948 v 37 No. 1 1-15 25 figs. [32 refs.]

The author states that the excretion of urobilin by patients suffering from pernicious tapeworm anaemia (due to *Diphyllobothrium latum*) has not been systematically investigated. He therefore studied it in 19 patients suffering from this form of anaemia, with 6 healthy subjects as controls. A complete blood picture was first obtained. The tapeworms were then expelled with filicium and Epsom salts. Three days were then allowed to eliminate the effects of the filicium on the liver. The amounts of urobilin excreted in the faeces and urine during each 24 hours were then determined by the spectrophotometric method of HEILMEYER, and HARRIS (*Biochem. Ztschr.* 1931 v 231 303) and also by the reduction method of TERWIL (*Dtsch. Arch. klin. Med.* 1923, v 149 72). [In text given as Terwin.] Each morning during the tests the reticulocytes were counted. The diet of the patients was kept as uniform as possible. Errors due to the following causes were as far as possible eliminated: disorders of the liver, organic heart diseases, infections likely to cause hepatitis, haemolytic conditions likely to cause increased excretion of urobilin, extra oxidation of blood, diarrhoea, acid fermentation in the bowel and abundance of chlorophyll in the faeces.

The results obtained with the 6 healthy and 19 anaemic subjects are described and illustrated with graphs. The author concludes that the urobilin excreted by the 6 healthy subjects during 24 hours was 75 to 180 mgm in the faeces and 0.4 to 2 mgm in the urine.

The urobilin excreted by the anaemic patients generally increased before liver treatment, it varied between 200 and 540 mgm. in the faeces and between 2.5 and 10 mgm in the urine during the 24 hours. After adequate liver treatment the urobilin excretion rose in all the anaemic patients, rising in one patient to 1,040 mgm in the faeces and 36 mgm in the urine in 24 hours, after which it fell to normal.

This increase of urobilin after liver treatment seemed in these cases to last 10 to 19 days, with an average of 14.8 days, starting one or two days after the rise of the reticulocyte count and ceasing in 2 to 5 days, with an average of 3 days, after the reticulocyte response. The author thinks that this suggests that the haemolysis is a secondary factor in the genesis of pernicious tapeworm anaemia, because the signs of haemolysis vanished with the improvement in the bone marrow which followed the liver treatment. The maximum of urobilin excretion was reached slightly after the reticulocyte peak and from then onwards slowly decreased. For reasons given in the paper, the author concludes that the time required for the urobilin to rise and become normal again represents the life-span of the megalocytes, and he concludes that this life-span is 7-14 days.

BASNUEVO, J. G. Teniasis y estaño (II). [Tin in the Treatment of *Taenia saginata* Infestation.] *Rev. Kuba Med. Trop. y Parasit.* 1948, June, v. 4, No. 6, 119-21. English summary.

A patient who had received 16 treatments with different drugs unsuccessfully on account of infestation with *T. saginata* during 24 years, was given by the author tablets containing the metal and salts of tin, each containing powdered tin 0.25 gm., tin protoxide 0.04 gm. and the chloride 0.001 gm. He was given 10 tablets (which he calls Solitaricide Kuba) on each of two successive days and he passed a tapeworm 7 metres in length. The scolex was not found, but 14 months later neither ova nor proglottides had been seen in the faeces. Ten patients were treated in this way and 6 were cured. Later, the following was the scheme of treatment. A saline purgative the evening before, next morning, 5 tablets before any food was taken, and 5 more every half hour till 20 tablets had been taken in all. Six hours later light food was given and at bedtime that evening a purgative. During the ensuing 4 days 5 tablets are taken daily, making 40 altogether. For children, the dose is 1 tablet for each year of age up to 10, over 10 years the same dosage as for adults, and for the 4 following days 1 tablet for every two years of age.

Seven patients were treated by the 40 tablet method, 3 were certainly cured, 3 were apparently cured. For three months later examination revealed no signs of infestation. In none was the scolex found and it is thought that, though the worm is killed, the scolex has clung to the mucosa and does not pass out with the faeces. [See also this *Bulletin*, 1948, v. 45, 921.]

PASSOS, W. & BARBOSA, V. de C. "Syngamus laryngeus" na especie humana. [Human Infestation with *Syngamus laryngeus*.] Rev. Brasileira Med. Rio de Janeiro. 1948 May v 5 No. 5 340 1 fig

A woman 45 years of age complained of a dry obstinate cough of three months duration. On examination of her throat a small red spot was seen which was thought to be a foreign body—a fragment of coloured cotton—and the patient was asked if she was in the habit of biting off her cotton when sewing. To the examiner's surprise the spot was seen to move and a worm was extracted which proved to be *Syngamus laryngeus*—a genus occurring in sheep, cattle, goats and birds, but exceedingly rarely in man. The symptoms cleared up at once and have not recurred. No suggestion is offered as to the mode of acquisition of the parasite in this case. H. Harold Smith

KLUSING, H. W. Een geval van *Ascaris lumbricoides* in de tuba. [A Case of *Ascaris lumbricoides* in the Fallopian Tube. Nederl. Tijdschr. v. Geneesk. 1948, Sept. 4 v. 92 (III) No. 34 2758-8.

The English summary appended to the paper is as follows —

"Description of a case of *ascaris lumbricoides* in the right Fallopian tube in all probability the worm had left the intestine via the appendix.

The remarkable thing about this case was the cyclic course of the symptoms which stretched over a period of four months and the close connection of the symptoms with the menses."

PINTO, A R & DE ALMEIDA, C L Contribuição para o estudo das filariasas da Guiné Portuguesa. [A Study of Filariasis in Portuguese Guinea] *An Inst Med Trop Lisbon* 1947, Dec, v 4, 59-89, 25 figs (1 folding map) [14 refs] English summary

In this study the authors had in view (1) Investigation of the details of the periodicity and of the proportion of persons infested among those with elephantiasis and those infested who presented no objective signs, (2) Identification of the transmitters, (3) Study of the clinical aspect and the incidence by age and sex, (4) Finding out what filariae other than *Wuchereria* were present and to what extent, in the district. A line map indicates the district investigated and photographs illustrate the terrain and the dwellings and patients showing enlarged glands, especially in the groin, and various stages of elephantiasis of the legs and scrotum.

A list of the chief diseases met with during examination of 6,227 Africans gives 134 with conjunctivitis, 130 with urinary schistosomiasis, 68 with enlarged glands, 64 with scabies, 40 with umbilical hernia, 34 with leprosy, only 28 with hookworm, and 21 with sleeping sickness. Blood samples were taken at night from 986 of different ages and either sex, whether they did or did not show signs of filarial infection, 485 (49.2 per cent) had filarial embryos in their blood. Of 172 positive who were examined again 130 had microfilariae in both day and night specimens, 42 in night specimens only. Five patients had their blood taken every two hours and the peak was seen to be between 10 p.m. and 2 a.m. Subjects with no objective signs harboured microfilariae in their blood more than those with signs, in a proportion of 7 to 5 (68 and 47 per cent), only 20.6 per cent of those with elephantiasis were blood-positive. *Anopheles gambiae* seemed to be the chief vector—it was by far the commonest mosquito, 95 per cent of nearly 2,000 captured, *Culex fatigans* only 2.5, *Aedes aegypti* 0.1 and *Taeniorhynchus* sp. 1.4 per cent, only one of *C. fatigans* was found infected, but 5 of the 28 *Taeniorhynchus*.

At all ages from infants to old people, enlargement of the epitrochlear glands was the commonest sign (between 58 and 70 per cent) and, next, inguinal adenitis in 29 to 40 per cent. Elephantiasis was not very common, in some districts only 1 per cent of the infested, and in none over 10.2 per cent.

As regards other filariae, 1,154 specimens of blood were examined for *Acanthocheilonema perstans* and the embryos were found in 36 (3.1 per cent), 28 were among 460 preparations from males (6 per cent), but only 8 among 658 females (1.2 per cent).

H Harold Scott

GALLIARD, H, HUARD, P & NGU, D V Recherches sur la filariose a *Wuchereria bancrofti*. Effets de l'intervention chirurgicale et de l'extirpation des filaires sur le rythme de la périodicité et sur la persistance des microfilaries [Effects of the Extirpation of *Wuchereria bancrofti* on the Rhythm of Periodicity and Persistence of Microfilariae] *Ann Parasit Humaine et Comparée* 1947, v 22, Nos 5/6, 332-44, 6 figs

The phenomenon of periodicity appears complex judging by the number of hypotheses which have been formulated—mechanical, physiological and biological—as affecting the host-parasite association.

The presence of great numbers of patients with filariae in Hanoi served to stimulate research on the effects of surgical operation upon periodicity. Special attention was directed to the influence of castration of female filariae upon the numbers of circulating microfilariae. The serious nature of the operation precluded the carrying out of periodic daily blood examination but nevertheless curves were worked out from counts of microfilariae 4 days before and 3 days after operation and thenceforward at stated intervals. In every case a count was made at 11 a.m. and again at 11 p.m. The eight patients were all males and were suffering mostly from filarial disease of the genital organs.

In the first case a general anaesthetic was administered but no operative procedures were undertaken but neither the rhythm nor the periodicity of the microfilariae (*Brucifilia*) was disturbed.

In the second, radical cure for hernia brought about a diminution of the curve and retardation for twenty four hours, but with complete restoration to its former level on the fourth day. The third was rather a similar case and a modification of the curve ensued, with delay of the maximum peak, but without any reduction in the total number of microfilariae.

In the fifth case (bilateral orchio-epididymitis with fistula) five living female filariae were recovered, after which a return of periodicity was noted with gradual return to normal nocturnal rhythm 18 days after operation.

In the sixth (hydrocele of six years' duration) ten female filariae were found in lymphatic varices and in the eighth with a similar affection six were recovered. In case seven no adult filariae were found, but after epididymectomy the count was reduced for 4 days.

These three latter were especially important because a primary alteration of rhythm was most marked. In case 6 the maximum peak was postponed for four hours. In number 8 a diminution of microfilariae was noted within two hours on the evening of the operation, but with a return to normal on the 16th day. In one case only (5) there was complete disappearance of microfilariae for 12 days, but with ultimate restoration of the level recorded before operation.

Thus it will be seen that operative interference whether entailing destruction of a number of parturient females or not, exerts no effect upon the number of microfilariae nor upon their periodicity.

Estimations upon the blood eosinophilia failed to show any effect upon the percentage of these cells.

General anaesthesia by itself appears to be incapable of producing even a temporary depressing effect upon the microfilarial curve. Destruction of a considerable proportion of the total number of adult female filariae even if the patient is in a state of hyperfilariaemia has only a negligible effect upon the total circulating microfilariae and this certainly presents an a puzzling puzzle. Finally it seems that surgical shock and physiological disturbance are capable of exerting the most immediate and prolonged dislocation of microfilarial rhythm.

The English summary appended to the paper is as follows —

" In subcutaneous ulcers of a 45 year old woman patient specimens of *Filaria volvulus* (*Oncocerca volvulus*) were found. The patient appears to have been infected in tropical West-Africa.

" Symptomatology, diagnosis, occurrence and treatment of oncocerciasis as well as the observations known from literature are discussed "

DEJOU L. Kystes suppurés et abcès chroniques par vers de Guinée.
[Suppurating Cysts and Chronic Abscesses caused by Guinea Worms]
Bull Soc Path Exot 1948, v 41, Nos 3/4, 200-202

Cysts caused by guinea worms can develop slowly and like cold abscesses. They may be all the more difficult to diagnose because they may develop in patients who have never expelled a guinea worm or have done so only several months or years previously. The author records three cases which illustrate this statement, one of his own and one presented by each of two other medical men.

The first patient, aged 20, was admitted with a diagnosis of a teno-synovial cyst on the posterior aspect of the lower third of the right forearm. It was a large, fluctuating, cold, painless swelling, adherent at its base, which had developed during the past year after fever and headache, but had never been painful. Puncture of the swelling yielded thick, sterile pus containing polymorphonuclear cells and lymphocytes. Dissection revealed a sac adherent to the superficial aponeurosis of the limb. The sac had two walls, the histological features of which are briefly described. In the pus a fragment 10 cm long of a degenerate and partly calcified guinea worm was found. No microfilarial larvae were discovered.

The second patient, aged 40, had a similar swelling of the anterior aspect of the right forearm, but this was covered with oedematous and infiltrated skin. The swelling had developed in two months and it obstructed the movements of the fingers, which were in a state of irreducible flexion. This swelling went deeper and from it came abundant pus in which were found a fragment of a flattened guinea worm and immobile microfilariae. The patient had expelled numerous guinea worms several months earlier.

The third patient, aged 25 years, had a swelling at the level of the left spermatic cord and had suffered from total impotence for six months. The cyst was removed and three weeks later the patient experienced erections. The histological structure of the wall of the cyst is described. In the cyst was an almost intact, but apparently dried up, guinea worm.

DEFICIENCY DISEASES

- 1 BLANC, F & SIGUIER, F. A propos de 8 cas de pellagre observés au cours de dysenteries amibiennes chroniques. [Eight Cases of Pellagra in Patients with Chronic Amoebic Dysentery] *Bull et Mém Soc Méd Hôpit de Paris* 1947, Nos 23, 24 & 25, 630-36

- 11 — & — Les pellagres post-dysentériques. [Post-Dysenteric Pellagra] *Ibid* 636-42 [Refs in footnotes]

1 In two patients with chronic amoebic dysentery there was a sudden onset of painful erythema of exposed parts, with aphthous stomatitis and mental symptoms—irritability and depression. Rapid relief was produced by a single injection of nicotinamide (250-500 mgm). The response to treatment, together

with the clinical findings suggested a diagnosis of pellagra. Brief mention is made of six other cases of amoebiasis, in which erythema of the limbs or aphthous stomatitis were cured by nicotinamide.

ii. Since in none of the cases was there a history of a deficient diet the pellagra was attributed to malabsorption. All the patients suffered from chronic and severe diarrhoea, with 15 to 30 stools a day. This did not respond to nicotinamide but was relieved by anti-amoebic treatment. In spite of the diarrhoea the patients were generally well nourished, and showed no signs of deficiency states other than pellagra. It is suggested that, in order to avoid this complication, patients with amoebic dysentery should be given a good mixed diet, and not a severely restricted one.

J. C. Watelore

GOUXELLE H. Pellagre et carences d'apport. [Pellagra and Contributory Deficiencies.] *Bull. et Mém. Soc. Méd. Hôp. de Paris*, 1947, Vol. 30/31, 911-14. [1st refs.]

The authors refer to the papers by Blanc and Siguer (above) and suggest that deficiency of nicotinamide may not be the sole cause of pellagra. During the war they studied an epidemic of pellagra occurring among the inmates of an institution, and compared the diet of the patients with that of the average citizen of Paris. The institutional diet contained slightly more nicotinamide than that of the Parisians but less fat and animal protein (see also MONTAIGRO *et al.*, this *Bulletin* 1947 v. 44, 340. ATKROYD and SWAMINATHAN *ibid.* 1940 v. 37, 97).

Such observations suggest that deficiency of amino-acids as well as of nicotinamide may play a part in the genesis of pellagra. This view is supported by the demonstration, both in experimental animals and in man of a metabolic relationship between nicotinic acid derivatives and tryptophan. (FRIEDLÄNDER *et al.* *J. Biol. Chem.* 1947 v. 167, 511. LUCKE *et al.*, *J. Nutrition* 1947 v. 33, 251. BRENN *et al.*, *J. Biol. Chem.* 1948, v. 182, 463).

HAEMATOLOGY

GIRDWOOD R. H. Anaemia and Marasmus in Indian Troops on Active Service. *Trans. Roy. Soc. Trop. Med. & Hyg.* 1948, July, 42, No. 1, 63-82. [22 refs.]

An investigation into the cause of anaemia and marasmus among Indian troops was started in the early part of 1945. The haemoglobin percentages of the bloods of 500 Indian soldiers passing through a transit hospital in Bengal were ascertained. The mean of the group was 14.17 gm. per 100 ml. 7.4 per cent. were below 8 grammes and 11 per cent. below 11 grammes. There was no significant difference between the meat-eaters and the non-meat-eaters, nor between groups arranged according to length of service with the exception that those with less than a year's service had only 11.89 gm. per 100 ml. which was significantly lower than the rest. However this group was almost entirely composed of men from a Pioneer unit which had a strikingly low mean haemoglobin percentage.

During July 1945 83 cases from east of the Brahmaputra river were admitted to a special anaemia centre. Stool examinations for a worm were carried out by a concentration method in 61 cases, and in 25 (41 per cent.) ancylostomiasis was found (weight of infection not stated). The mean haemoglobin concentration of the 25 patients with hookworm infection was significantly lower than that of those with no ova in their stools.

Haematology

Vol 45, No 12]

One hundred and twenty-four Indian other ranks suffering from the marasmus syndrome were investigated. The haemoglobin findings in 27 are reported. All but one came from east of the Brahmaputra river and the average duration of symptoms was 17 weeks. Data regarding food supply was unsatisfactory. 84 of the group were meat-eaters, but supplies of fresh meat were negligible in the jungle areas. Most of them had had malaria, a record of the finding of parasites was obtained in 51 cases, and all but 6 had received mepacrine regularly. "There was nothing in the history of these men to suggest that either bacillary or amoebic dysentery played a part in the onset of their illness." Stool examinations in 88 cases revealed ancylostome ova in 27, *E. histolytica* (vegetative form) in 4 and cysts in 1, other protozoa and helminths were found, but 44 cases were negative.

The commonest clinical features were diarrhoea (83), flatulence (75), anorexia (70), abdominal pain or discomfort (69), vomiting (60), fever (44), glossitis, marked evidence of loss of weight (52), palpable spleen (33), and marked dryness of skin (33).

"According to the findings of the absolute indices, the distribution of the types of anaemia in the cases under consideration was as follows: orthochromic macrocytic, 17; hypochromic macrocytic, 8; hypochromic orthocytic, 2."

Megaloblasts indistinguishable from those found in pernicious anaemia, except that haemoglobinization of the intermediate megaloblasts was less advanced, were found in the sternal marrow in 62 out of 96 cases. Many patients had shown resistance to treatment with crude liver extract by intramuscular injection in their previous hospital treatment. In some of these cases megaloblasts still persisted. Liver injections, with the addition of mepacrine therapy, were given in 8 cases, significant improvement only occurred in 2. The liver injections, however, appeared to precipitate an attack of malaria in each of five of these cases. Neither folic acid nor protolysed liver was available at the time of the investigation.

The author gives no "conclusions", nor in the "summary" is there any expression of opinion on the aetiology of the condition. The following quotation might possibly be taken as his tentative opinion on the aetiology of the anaemia, but it appears to have little connexion with the data he has presented —

"It is evident that the anaemia described in the present series of cases is of a very complex type. Possibly years of primary malnutrition prior to joining the Services played a part in many cases, and was aggravated more recently by supply difficulties during jungle fighting. Thus there might be a deficiency of Wills's factor, and conceivably of extrinsic factor, which would give a tendency to megaloblastosis. In addition, there was a sprue-like condition, which itself might induce a megaloblastic form of anaemia due to malabsorption of the liver factor produced by the interaction of Castle's extrinsic and intrinsic factors, or of folic acid conjugate (Davidson, and Girdwood, 1947). To what extent prolonged low intake of protein of high biological value plays a part is unknown."

"Malarial infection, when present in men suffering from such a deficiency syndrome, might add a haemolytic element, and thus increase the megaloblastosis in the manner described above."

AIENGAR, N A, NAIDU, B R L, KRISHNAMURTHY, C B & RANGANNA, B
Observations on Anaemia in the Malnad Parts of the Mysore State *Indian Med Gaz* 1947, Aug, v 82, No 8, 488-93, 10 figs on 1 pl

"Anaemia associated with nutritional deficiencies, malaria and hookworm disease is severe and widespread in the Shimoga and neighbouring districts of

Mysore where the average diet appears to be extremely poor in proteins and fat. Some 2,000 patients were studied in hospital during four years, and approximately one third of the patients had total erythrocyte counts of less than 1½ million per cmm. Treatment consisted initially of liver extracts iron and quinine. Vermifuges were given later when the patients' condition had improved. The results of such treatment appeared disappointing, and the real remedy would seem to lie in fundamental measures to raise the standard of living and of education in the affected regions. *F. Margatroid*

BAUER, J. Sickle Cell Disease. Circulatory Stasis in Small Blood Vessels. *Acta Med. Scand. nordica*. 1947 Oct 15 v 129 No. 1 1-11

This paper contains nothing new but emphasizes that the important pathological process in sickle cell anaemia is the circulatory stagnation caused by deformation of the erythrocytes, which produces haemolysis, thromboses, and ischaemia of the tissues with later endarteritis and fibrosis in the affected area. *F. Margatroid*

VENOMS AND ANTIVENENES

DEL POZO E. C. The Action of the Venom of a Mexican Scorpion (*Centruroides noxius* Hoffmann) on Cholinesterases. *Brit. J. Pharmacol. & Chemotherapy* 1948 Sept., v 3 No. 3, 219-22, 1 fig

"The effects of extracts of the venom of a Mexican scorpion (*Centruroides noxius*, Hoffmann) were examined on cholinesterase preparations with the view of finding out if the eserine-like effects this venom exerts on isolated tissues and in animals on intravenous injections could be explained by a cholinesterase inhibiting property. The venom extract was only found to inhibit pseudocholinesterase as well as true-cholinesterase when present in very high concentrations. It is concluded that the symptomatology of the venom poisoning is independent of or dependent to a very slight degree only on inhibition of cholinesterase

DE MAGALHÃES, O. Combate ao encurponismo. Nota prévia. (Dealing with Scorpions.) *Bras. de Medicina*. 1948, Apr 17 & 24 v 62, Nos. 16/17 169-70.

The author describes the results of Gammexane on scorpions in Brazil, notably the *Tityus bahiensis*. The substances used were the fluid LG-140 which contains 10 per cent. of the gamma isomer by weight and is diluted 1 in 20 with kerosene or the powder D-034 (which contains 0.5 per cent. of the isomer) 1 gm. emulsified in 30 gm. of kerosene. After contact for 1.5 minutes the scorpions die in 20 minutes or so. The symptoms seem to be in three phases. In the first, though poisoned they show nothing definite, then they become very excited and agitated, running from one side of the containing box to the other, tails erect and striking at everything within reach around them. This is followed by the third phase of ataxia and paralysis in which they run about in a disorderly manner, are ataxic with generalized tremors or move in small circles before becoming paralyzed. Gammexane should prove very serviceable in dealing with dangerous scorpions in Brazil. *H. Harold Smith*

AMÉRICA MED. 1948, July v 5 No. 4 54-61. Modern Treatment of the Bites and Stings of Small Desert Animals.

(This is a sort of Brains Trust on medical problems, or a reply to the 'Any Questions' section of the *British Medical Journal*. An actual case is

recorded and a team of six, whose qualifications to reply are detailed, is named, each member of which expresses his opinion on the diagnosis and treatment.]

A child of 8 years was bitten on the ankle by something unknown. He was taken to hospital and 30 minutes after infliction of the injury there was an area of redness 2 inches above the right ankle and a single indistinct puncture wound, but no discoloration. The child was conscious, nervous and restless [in fact, there seems to have been little wrong and much of the child's symptoms might have been due to parental panic]. The members of the panel gave their opinions in turn, taking into consideration scorpion sting, spider bite, especially *Latrodectus mactans*, a small rattlesnake, a centipede [with a single puncture?], tarantula, Gila monster, coral snake, bee, wasp, or red ant sting. The treatment of each of these—first aid by a tourniquet, local application of cold, incision (if no doctor is near), stimulants for shock, and specific treatment by antivenenes and anti-histamine drugs—is stated by different members of the team, but in rather general terms. [The principle of the series is that any doctor confronted by a difficulty can send it up for discussion by specially chosen consultants. If urgent, a reply is sent direct, without waiting for publication.]

DERMATOLOGY AND FUNGUS DISEASES

MORTA, L da C. *Paracoccidioides Granulomatosis*. Cardiac Localization in a Case of Generalized Form. *Amer J Path* 1948, Mar, v 24, No 2, 323-37, 12 figs on 3 pls [20 refs]

The author gives a fully documented account of the history and nomenclature of the fungus *Paracoccidioides brasiliensis* (Splendore) Almeida 1930, followed by a discussion of the clinical features of the South American and North American types of blastomycosis, which are clearly differentiated from each other. He points out that the cutaneous lesions in the South American disease are invariably secondary, and are due to dissemination of the fungus from some deeper focus. He agrees with other observers that the primary lesions occur on the bucco-pharyngeal mucosa in the form of granulomatous ulcerations frequently of a papillomatous or vegetative character, which indicate an oral path of infection. From these lesions the infection reaches the cervical lymph nodes and extends to the supraclavicular, axillary and other groups, constituting the "lymphatico-tegumental" form of the disease. From 3 to 18 months later a general dissemination of the parasite through the blood stream may occur, causing cutaneous and visceral lesions, which may affect nearly all tissues of the body, and death soon follows.

A detailed account is given of the post mortem examination of a case of the generalized disease in which the fungus was found in destructive lesions of the cardiac musculature, and in its actively reproductive form in the lumen of a cardiac blood vessel, indicating a "septicaemic" state. Both of these are original observations.

LACAZ, C DA S, ASHCAR, H, COSTA, O & VIOTTI, M R. Ação da estreptomycina 'in vitro' sobre o paracoccidioides brasiliensis. Ensaio terapêutico na blastomycose sul-americana. [Action of Streptomycin *in vitro* on *Paracoccidioides brasiliensis* and Attempts to use it in the Treatment of South American Blastomycosis]. *Hospital* Rio de Janeiro 1948, May, v 33, No 5, 693-703, 2 figs [10 refs]

The authors study the action 'in vitro' and 'in vivo' of streptomycin upon *Paracoccidioides brasiliensis*, agent of South-American blastomycosis.

High concentrations (5,000 U. to ml. and onwards) of streptomycin inhibit growth of *P. t. anisurus* at its lag phase or phase of logarithmic growth. Lesser concentrations have no effect upon *P. brasiliensis*. The authors verified that this fungus may have an inhibitory action upon streptomycin. After the studies in vitro the authors made use of streptomycin in a case of generalized ganglionic blastomycosis. 29 gra. were employed on the whole (1.5 gra. daily). The lesions did not recede with this treatment but general conditions of patient remained stationary. The observation is drawn to a close by showing streptomycin's low therapeutic value in cases of blastomycosis. Sulphonamide preparations are still the therapeutics to be relied upon.

LITTMAN M. L., WICKER, E. H. & WARREN A. S. Systemic North American Blastomycosis. Report of a Case with Cultural Studies of the Etiologic Agent and Observations on the Effect of Streptomycin and Penicillin in Vitro. *Amer. J. Path.* 1948 Mar v 74 No. 2, 339-65 11 figs. on 5 pls. [19 refs.]

The authors describe a case of systemic blastomycosis, of the North American type in a male negro aged 20. The signs and symptoms were mild afternoon pyrexia with night sweats and blood-streaked sputum and an X-ray picture of miliary nodules scattered throughout both lungs. These seemed to justify the diagnosis of pulmonary tuberculosis, although the tubercle bacillus had not been found in the sputum. The development of multiple tender cutaneous nodules might have suggested another disease but the onset of mental symptoms with signs of an intracranial lesion prompted the diagnosis of tuberculous meningitis. Before death however *Blastomyces dermatitidis* was found in the pus of a subcutaneous abscess.

A brief account is given of the post mortem findings, the most interesting of which was the lesion on the brain. In the region of the superior sagittal sinus the under surface of the dura mater was closely adherent to a yellowish friable mass, 2 to 1" mm. deep and about 3 cm. wide, consisting of a granulation tissue and inflammatory exudate of polymorphonuclears, lymphocytes, plasma cells and macrophages, with numerous spherules of the fungus *B. dermatitidis*. The brain cortex was necrosed to a depth of several millimetres over the mesial and upper surfaces of the occipital and parietal lobes, and the leptomeninges on the base of the brain, the cerebellum, pons and medulla oblongata were covered by a tenacious, thick yellowish-green exudate.

In the primary cultivation of the fungus from pus colonies were obtained on blood-agar after 4 days incubation at 37°C., but, on glucose-agar at room temperature a more typical mycelial form developed in from 7 to 16 days.

Two strains of *B. dermatitidis* were found to be resistant to penicillin and streptomycin in culture when these antibiotics were present in the culture medium at a concentration of 200 units per ml. J. T. Duncan

TROPICAL OPHTHALMOLOGY

A REVIEW OF RECENT ARTICLES LI*

Blindness—The report on *Blindness in British African and Middle East Territories*¹ is divided into three parts

Part I deals with statistics of blindness, the social condition of the blind, the medical services, the causation of blindness, education of the seeing and the blind, and the training, employment and after-care of the blind

Part II deals with a scheme of blind welfare, the administrative organizations capable of giving effect to a plan of development, voluntary organizations, finance, registration of the blind, prevention of blindness, propaganda, education of the blind, vocational training, employment and Braille production

The Appendices give details of the institutions for the blind in the Colonies visited, registration, a description of a Colonial medical department, a mobile ophthalmic unit, curriculum in a school for the blind, native industries suitable for the blind, Braille printing unit for colonial use

The investigation carried out by the Joint Committee appointed by the Colonial Office and the National Institute for the Blind reveals that there is a real problem of blindness in the Colonies and that seventy-five to eighty per cent of the blindness is preventable The report suggests a scheme of prevention of blindness, treatment of blindness and the education, training and employment of the young blind This scheme can be put into operation without delay and has possibilities of wide expansion

The Report is an excellent summary of the blind problem in British African and Middle East territories, and by those interested in the subject it should be read *in toto*

The causes of blindness in *China* are discussed by FLOWERS² It is generally agreed that the incidence of blindness is high, but it is strange that so little has been written on the possible causes of this high incidence The surveys on which we are mainly dependent for evidence cover hospital out-patients in particular centres and are made by busy ophthalmologists Valuable and reliable as these are, they can only give us part of the story and cover only a short span of time

From the statistical reports of CHANG, CUNNINGHAM [*Bulletin of Hygiene*, 1937, v 12, 208], SHEN, and LING [*this Bulletin*, 1924, v 21, 459, 983] it would appear that the following diseases are the most important causes of blindness in China

(1) Ulcerative keratitis of unknown origin In all the reports, a high proportion of eyes are blinded by this disease Acute conjunctivitis, including the damaging muco-purulent form, is one of the most frequent eye diseases seen in the average hospital in China and is the original cause of most of the corneal ulcers The organisms which are most frequently found are the Koch-Weeks bacillus, the pneumococcus, and the gonococcus Muco-purulent conjunctivitis is commonly associated with trachoma, the one aggravating the other

Causes of Blindness in China *Chinese Med J Shanghai* 19

(2) Trachoma. Along with Egypt and India, China must be regarded as the home of trachoma and this disease must be considered as one of the major causes of blindness if not the principal one. A very high proportion of China population is infected with either acute or chronic trachoma which produces blindness directly from its numerous complications or sequelae or by providing the fertile soil on which more acute infections flourish. It is probably not the most important cause of blindness in the young. Its damaging effects are mainly produced in adults as a result of prolonged irritation and scarring.

(3) Phlyctenular conjunctivitis. Lung regards this disease next to trachoma, as the most common eye disease affecting young people of either sex. It often attacks both eyes and tends to recur over a period of months or years. The disease is an expression of the debilitated constitution of the patient and is mainly found among the poorer classes. In the majority of cases the Mantoux tuberculin test is positive.

(4) Syphilis. It would appear that this disease is not a common cause of blindness and that congenital syphilis is a comparatively rare disease. It is probable that in the large cities nearer the Eastern seaboard, where syphilis is so widespread, it is a much more frequent cause.

(5) Keratomalacia. This disease must be regarded as one of the important causes of blindness in children under ten years of age and is due to the prevailing malnutrition resulting from war.

(6) Gonorrhoea. Many infants lose their vision from this disease as a result of delivery by untrained midwives. Credé's prophylactic treatment of instilling a weak solution of silver nitrate drops in the eyes of new born babies immediately upon delivery is not generally practised in China. Blindness in adults from acquired gonococcal infection is however much commoner than that from ophthalmia neonatorum but it is highly probable that large numbers of infants lose their sight from this cause but are never referred to hospital for diagnosis and treatment.

(7) Acute infectious fevers, smallpox and measles. These diseases are probably not uncommon causes of blindness particularly in the north and in country districts but the figures produced by different writers are conflicting and the true picture will only be ascertained after fuller surveys have been carried out.

(8) Trauma. Since the large majority of China's population are agriculturalists there is comparatively little traumatic blindness.

(9) Cataract. This is probably the commonest cause of blindness in old people and a high proportion of cases are complicated by the lesion resulting from chronic trachoma.

(10) Glaucoma. This is also a fairly common cause of blindness among the adult population. In a large number of cases the disease is undiagnosed and when the patients present themselves for treatment the condition is inoperable.

(11) Hereditary and congenital defects. These are considered to be uncommon factors in the causation of blindness in west China.

The indirect causes of blindness in China may be summed up as ignorance, poverty, malnutrition, neglect of vaccination against smallpox and the lack of adequately trained midwives to safeguard the eyes of the newly born.

Surgery.—Recent advances in cataract surgery as reviewed by Gill³ He advocates the following technique for the extraction of the lens in capsule. The pupil is dilated by instilling two drops of 0.5 per cent scopalamine hydrobromide in the conjunctival sac. Albinism produced by the anasthetized eye is not used. The lid is held open by silk sutures. The upper suture is placed under the superior rectus muscle 4-6 mm. behind its insertion.

Gill, F. Cataract Surgery. Recent Advances. Southern Med J 1948, Mar 41, No. 3, 191 & 204 pp. [14 refs.]

The lower suture is placed through the skin of the lower lid near the lid margin. A full 180 degrees concentric conjunctival flap is dissected down 3 mm from the corneal limbus. Double-armed corneo-scleral sutures are placed at 1 and 2 o'clock with No 60 silk in atraumatic needles. Conjunctival sutures are placed at 10, 12 and 2 o'clock. The section is made at the limbus with a specially devised keratome which is 14 mm in width at its base. The incision is widened to the horizontal meridian with scissors. If an iridectomy has been decided upon, it is performed at this point. The final step in the operation is the extraction of the lens in capsule by the head-on or Verhoeff method. The zonular fibres are ruptured by point pressure at 4, 6 and 8 o'clock. Gentle pressure is made on the iris at 3 and 9 o'clock with a small iris retractor. Firm continuous pressure is made on the limbus at 6 o'clock. When the lens presents itself in the wound it is grasped by Verhoeff capsule forceps and delivered by continuous pressure from below. The sutures are then tied and 1 per cent atropine is instilled in the conjunctival sac. The patient is generally allowed out of bed twenty-four hours after operation. The author claims that by this technique 90 per cent of his cases achieved a visual acuity of 20/25 or better. Haemorrhage has been reduced to 3 per cent and vitreous loss to 2 per cent.

A new operation for entropion and trichiasis of the upper eyelids is described by MASCATI⁴. The technique is as follows. Before commencing the operation, the surgeon should study very carefully the arrangement of the displaced lashes and should keep in mind their position. A light scratch with a very sharp knife is made, parallel to the upper lid margin, slightly above the position of the hair follicles. The ends of this scratch should extend a little farther away than the last mal-placed hair on either side. This scratch is meant only as a mark and should not include the whole thickness of the skin. A second scratch is made below and parallel to the first and the incision goes right down to the subcutaneous tissue. A third scratch is made above and parallel to the first one so as to include a strip of skin, the breadth of which should be about 2 mm more than the distance between the first scratch and the grey line. A fourth scratch is now made exactly on the grey line, splitting it to the length of the first scratch. A tunnel is made through the split grey line up to the first scratch. The strip of skin between the first and third scratches is freed from above and at the sides, leaving it only attached to the upper border of the first scratch. All subcutaneous epidermal tissues are removed from the freed strip to make it as thin as possible. The strip is then drawn through the tunnel and stitched to the grey line with interrupted sutures. The upper edge of the third scratch is then sutured to the lower edge of the second scratch.

Trachoma — Trachoma in Changsha, Hunan, is reviewed by Chen-Chung Wu⁵. This disease is one of the common chronic diseases in China and is also one of the most important medical and public health problems, since it causes blindness either directly or indirectly. Out of 1,340 outpatients attending the Department of Ophthalmology, National Hsiang-Ya Medical College and Hospital between September 1946 and March 1947, 1,017 (75.88 per cent) suffered from trachoma. Of these cases 29.43 per cent were mild cases, 67.26 per cent were moderate and 1.31 per cent were severe cases. The highest age incidence is between 10 to 40 years. Occupational incidence ranks highest among students and teachers, then merchants, housewives, etc. Most cases are in Stage 2 (MacCallum's classification) and moderately severe. A list of common complications and sequelae is presented, and pannus heads the list. Two hundred and sixty-five of the 1,872 eyes seen were blind.

Malaria.—Migraine due to malaria is reviewed by SÉDAN.⁶ He reports a case which had a bilateral scintillating scotoma followed by a temporary blindness. This was accompanied by a total paralysis of the right third cranial nerve. The fundus revealed lechaemia with spasm of the retinal arteries. The veins appeared normal. The macula appeared to be more coloured than the rest of the retina, probably more in contrast than effect. The case cleared up quickly on one intravenous injection of quinine. The paralysis lasted longer than the blindness, but the eye became normal by the end of the second week of treatment.

The author considers the case worthy of publication for the following reasons. Spasm of the retinal arteries as a result of malaria is very uncommon. Its association with an ocular palsy so far as he knows, has not been reported. The action of quinine in the cure of the blindness, the headache and the paralysis was remarkably rapid and so rules out the possibility that these complications are due to quinine therapy. Although these ocular manifestations are at the time alarming the author considers they are benign and clear up on treatment.

Leprosy.—A case of iridocyclitis leprosa imported into Denmark is described by HANSEN.⁷ In a man aged 41 years, who had spent 15 years in the East. He first developed a localized eruption of leprosy on the left upper arm. Four years later he developed a general eruption of the anaesthetic type and this was followed four years later by a bilateral iridocyclitis with increased tension and lepromata on the left iris. The ocular signs progressed in spite of improvement in the skin affection and the vision deteriorated. It was not possible to follow the further progress of the disease as the patient returned to the East.

The author points out that the eyes are often affected in leprosy and that these complications are serious. The cornea is the part of the eye most frequently attacked. Iritis is always found together with affections of the cornea and occurs after the cornea has been invaded. The iris may however be the seat of primary attack. The disease follows a slow relentless course with periods of improvement and exacerbation but the prognosis is grave and the presence of lepromata considered to be a special sign of the malignity of the disease. According to some authors, lepromata may be the first sign that the disease is passing from the tuberculoid to the lepromatous form.

Disagreement prevails with regard to the way in which the infection enters. Some assume the infection to be exogenous through conjunctiva and epibclera some that it is secondary to a nasal focus, but most authors on the basis of microscopy and clinical investigation consider that the infection is endogenous with a primary lesion in the anterior part of the ciliary body and at the circulus unius major from which it spreads to the iris, sclera and cornea, while the posterior part of the eyeball is rarely attacked. E. O'G. HUGHES

MACCHIARELLO A. El virus del tracoma y su cultivo en el saco yelmo del huevo de gallina. (The Virus of Trachoma and its Cultivation in the Yolk Sac of the Hen's Egg.) Reprinted from *Rev. Ecuatoriana de Hig. y Med. Trop.* Guayaquil, 1944 Apr v 1 N. 2, 33 pp. 106 refs.

Macchiarello's experiments which resulted in the culture of trachoma virus in the yolk sac of the hen's egg can be summarized as follows. The following standard abbreviations are employed.—I.B.—Initial body; intraciliary basophilic measure, 1.0–10 μ . P.H.—Prowack-Haller-Hartley body count type, 1a basophilic circular cell enclosing a mass of acidophilic elementary granules (E.H.). The P.H. measures more than 10 μ , the E.H. 0.5 to 0.3 μ .

6. Sédan, M. *Migraines ophtalmiques et étiologie des étiologies oculaires de la migraine.* *Ann. Ocul.* 1945, 64, 165–70.

7. Hansen, M. T. A Case of Iridocyclitis Leprosa. *Acta Ophthalmologica*, 1947, 25, N. 3, 265–6. [15 refs.]

(I) The source of the virus was a young man M A, aged 17, who had suffered from a disease diagnosed as trachoma for three years. When seen by the author this was in stage Trachoma II, with reddened conjunctiva and follicles. The cornea was not affected. Indigenous trachoma is not known in Ecuador although immigrants, usually Syrians, carry the disease. M.A. had not been in contact with such cases. Scrapings of the conjunctiva of M A showed the classical inclusion bodies.

Follicles removed from his conjunctiva were finely divided with scissors and emulsified in Tyrode solution. This emulsion was used unfiltered for the inoculation of seven eggs, in the yolk-sac according to Cox's method [see this *Bulletin*, 1942, v 39, 381]. The eggs had previously been incubated for 3, 6 or 9 days. On the 3rd day after inoculation, four of the eggs were examined. Three were found contaminated and were discarded, while study was concentrated on the fourth containing a 9-day embryo (*i.e.*, it had been incubated 6 days before inoculation). In films made from the wall of the yolk sac the following bodies were found: (1) Initial bodies, (2) larger basophil bodies containing acidophil granules, *i.e.*, P K, (3) rare E K, (4) free in the yolk a few vesicular P K were found. No traces of virus were found in the albumin, in the chorio-allantoic membrane or other membrane. *Cultures on bacteriological media remained sterile.* (II) The remainder of the yolk-sac of this egg was washed in broth, triturated in a mortar, re-suspended in Tyrode and divided into two halves, of which one was filtered through a Seitz E K membrane, the other left unfiltered. With each half, 8 eggs of 5-6 days incubation were inoculated.

The eggs inoculated with unfiltered suspension were found to be contaminated and were discarded.

Of the eggs inoculated with filtered suspension two were examined on the 6th day and showed a good development of virus. One was examined on the 23rd day (the embryo was then at term, having been delayed in development by the virus) and it showed abundant E K. In subsequent passages the most abundant infection was always found on the 23rd day. From this (filtered) source subcultures were made by Cox's method through 9 generations, the material being filtered if contamination appeared. The 9 generations occupied from the 5th January 1943 to the 7th March 1943.

Filtration of the emulsion of yolk-sac through a Berkefeld N or Seitz E K filter was successful if the virus had reached the stage of E K, but not if still in the plaque or morula (I B) stage. Retention was probably due to a matrix containing glycogen. [It should be noted that virus taken direct from the man M A proved unfilterable, that filterability began after infection of the egg.]

(III) Experimental transmission of trachoma from the egg to man. An emulsion of a yolk sac of the 9th passage which was rich in E K was filtered through a Berkefeld N candle. One drop of this filtrate was instilled into the eye of a boy aged 6 years. Six days thereafter there was reddening of both eyes with lachrymation and photophobia. These symptoms persisted for 3 days (from 7th to 9th) but were absent between the 10th and 14th days. On the 15th day after infection they recurred more severely and simultaneously in both eyes. The conjunctiva was intensely red and oedematous, lachrymation and photophobia were marked. Feverish reaction and diarrhoea lasting four days occurred. After the 21st day, there was considerable vascular infiltration of the cornea which appeared definitely opaque. Treatment with sulphathiazole was then carried out. At the end of two months from infection, the conjunctiva and cornea were nearly normal in appearance and after one year there was no change. Sight was perfect and there was no ptosis.

During the period of observation scrapings were taken daily from this child's eyes with the following results. From the 6th to the 10th day, during

the first period of conjunctivitis, no inclusions or virus bodies of any kind were found. From the 10th to the 13th days during regression, numerous free basophil dots and a few basophil inclusions were found. From the 15th to the 18th days the conjunctival cells were filled with granules of various sizes. After the 18th there were fewer I. B. inclusions, E. h. were beginning to appear in the centre of these bodies and by the 25th day they had become typical I. h.

Three times during the acute stage, on the 8th, 16th, and 19th days, cultures into eggs were made from unfiltered and from filtered secretion. Only the unfiltered material in the last two experiments proved infective. On the 7th day both eyes were washed out thoroughly secretion was collected and filtered through a Berkefeld V and injected into 4 eggs, all of which yielded a gr. at multitude of E. h. when examined between the 4th and 7th days.

[Dr Macchiavello is to be congratulated on the very interesting results of his work. But as there appears to be some doubt whether the disease with which he dealt was identical with trachoma of the Eastern hemisphere, the experiments should be repeated.]

F. H. Stewart

SORSA E FARO. A epidemia de tracoma no arquipelago de Cabo Verde. [Outbreak of Trachoma in the Cape Verde Islands.] *Gaz. Med. Portuguesa*. 1948 v 1 No. 1 191-5. English summary

In August, 1943, the author was sent to the island of Sal to investigate an outbreak of trachoma which had appeared among soldiers of the garrison. He found 349 cases 20 in native soldiers. Of the other 329 there were 157 in the first stage (of McCallan) 169 in the second, 3 in the third. So far as could be ascertained the first case had occurred at Praia, a town of the island of St. Iago and thence the infection had spread by manual contact by the common and promiscuous use of towels and other personal belongings, and by the agency of flies for the place was hot and dusty. The civil population could, naturally, not be isolated, but those with trachoma were confined to certain houses under supervision and careful hygienic conditions—careful washing of hands, towels, clothes, etc. restricted to personal use, keeping down flies and the treatment of patients with copper sulphate, nitrate of silver, sulphathiazole, cyanide of mercury and treatment of any concomitant disease.

H. Harold Scott

HEAT STROKE AND ALLIED CONDITIONS

LEE, D. H. H. & MACPHERSON, R. H. Tropical Fatigue and Warfare. *J. Appl. Physiol.* 1948, July 1 No. 1 60-72.

Much of the morbidity experienced in the tropics can be attributed to precise "tropical diseases" but there has remained a rooted conviction that there is a residuum of morbidity directly attributable to exposure to extremes of heat and humidity and to this the term "tropical fatigue" has been applied. This so-called "tropical fatigue" assumed considerable relative importance as a cause of disability in tropical warfare and about the middle of 1946 it was decided to investigate its nature and incidence amongst military personnel serving in the Southwest Pacific Area.

It appeared that if tropical fatigue existed it might be either a physical or mental phenomenon, or a combination of both. Since psychological methods of investigation did not appear suitable for use in a field survey it was decided to concentrate on the physiological aspects, and to treat mental aspects largely by a method of elimination.

The approach adopted was to record the opinions of commanding and medical officers as to the efficiency of personnel in relation to the length of tropical service, to measure by suitable tests their physical condition and to relate the measurements to the length of tropical service, and to estimate the importance of psychological effects by comparing physical deterioration with the loss of efficiency reported

To test cardio-vascular reactions to acute maximal exercise the Harvard Pack Test was used. The subject wears a pack weighing one-third of his body weight and steps up on to and down from a platform 16 inches high once every two seconds until he can no longer maintain the pace or until five minutes have elapsed. The index is then calculated from the quotient when the duration of the exercise is divided by the sum of pulse counts after the exercise

$100 \times \text{Duration in seconds}$

$I = \frac{\text{Twice sum of pulse beats counted 1 to } 1\frac{1}{2}, 2 \text{ to } 2\frac{1}{2}, \text{ and } 4 \text{ to } 4\frac{1}{2} \text{ minutes after cessation}}{\text{Duration in seconds}}$

It was concluded that there was a general lowering of efficiency in R A A F ground crew surveyed in tropical areas as compared with those examined near Brisbane. Beyond a slight initial loss of weight, the only objective evidence of deterioration in physical fitness was that given by the Harvard Pack Test Index which showed a net fall of 0.19 units per week of tropical service. This is a small effect but it may assume importance after 12 months or so. The index was significantly correlated with the subject's own estimate of his efficiency, and with length of previous tropical exposure.

There was an extensive incidence of skin affections.

It was evident to the authors that the degree of physical deterioration found was quite inadequate to account for the marked loss of general efficiency apparent in the ground crew. Members of the Australian military forces exposed to a physical environment no better than that to which the ground crew were subjected showed smaller loss of efficiency, and this is taken to support the conclusion that physical effects play a relatively small part in causing the deterioration observed. This leads to the conclusion that the major part of the deterioration is due to psychological causes.

The influence of various psychological factors is discussed, and it is remarked that, by attention to sound principles, psychological deterioration can be avoided, or reduced to a minimum, in civilian settlements in the tropics.

T. Bedford

TROPICAL ULCER

CATRYSE, R. M. Note sur le traitement de l'ulcère phagédénique tropical [The Treatment of Tropical Phagedaenic Ulcer] *Ann. Soc. Belge de Méd. Trop.* 1948, Mar 31, v 28, No 1, 1-5, 2 figs on 1 pl.

The author treats tropical phagedaenic ulcers by a method based on the technique of Winett-Orr. Under general anaesthesia, for which sodium pentothal suffices, the ulcer is vigorously curetted and the margins excised with curved scissors until a healthy bleeding surface is produced. Compresses of sterile vaseline gauze are then placed on the wound and the whole is enclosed in a plaster-of-paris-case, without window. Seven days later the plaster is removed and the wound is dressed for several days with mercurochrome and sulphanilamide powder, until it appears free from infection. In cases of large and heavily infected ulcers it may be necessary to repeat the curetting and plaster treatment. Finally the wound is covered with skin grafts, which are left undisturbed for 10 days.

The author has treated 41 cases by this method, with successful results in all cases although some of the ulcers were of 15 to 20 years standing.

[Treatment by occlusive dressings, after cleansing and applying sulphamids made powder was one of the methods recommended by the War Office for the treatment of desert sores during the 1939-45 war.]

H. L. Harnett

CASTELLANI A. Tropicaloid Ulcer (Myxoid Ulcer Superficial Tropical Ulcer). *Am. Inst. Med. Trop.* Lisbon. 1947 Dec. v 4 297-312, 14 figs. on 4 pls.

This is an amplified account of that given in the author's recent book on the Diseases of Africa (*Le Maladies de l'Afrique*) published in Rome in 1946. The condition differs in several respects from *ulcus tropicum*, velvet sore and other forms of ulcer though resembling them in some points (hence it is presumed, the name "tropicaloid"). Cases were seen by the author in Libya during the late war when he met with it under the names Marmarica ulcer or oasis ulcer. The causative organism isolated and named by the author is the *Mycrococcus myxoides* coccoid forms being 0.6-1 μ in diameter and cocco-bacillary forms 0.6-2 μ long and 0.3-0.6 μ broad. It is Gram-negative when first isolated but later becomes positive and yet later still returns to the Gram-negative state. It is usually found mixed with other organisms, staphylococci and diphtheroid bacteria. According to the author growth on Italian agar is not profuse and produces no pigment but on Portuguese or American agar a yellow pigment is formed. In liquid media, broth and peptone water growth is scanty; it does not liquefy gelatin. It produces acid in glucose, laevulose, lactose, maltose, saccharose and galactose, but not in mannitol, and no gas in any. Inoculation on the scarified skin of volunteers, or to small wounds, was followed in 10-12 days by typical ulcers which, like the natural ulcers, took 3 months or so to heal, leaving either pigmented scars or infiltrated plaques. Similar inoculation with the associated organisms resulted only in small inflammatory lesions which crusted over and healed completely in 2-3 weeks. The ulcer may be tender on pressure but is not usually painful. There may be one or four of them, usually in the leg, each 1-4 cm. in diameter with a reddish, granulating base and an inflamed periphery, edges not raised or undermined. There is no lymphangitis or corresponding lymphadenitis. Apart from the superficial types, nodular or more infiltrated types are seen and also recalcitrant crusted and pyodermic types. (In his book the author gives in more detail the points in diagnosis between this and other forms of ulcer: *ulcus tropicum*, velvet sore (Barcoo rot), yaws, leishmaniasis, leprosy, mycotic ulcer, varicose, syphilitic, tuberculous and trophic forms.)

The best treatment seems to be the simple one of rest, basic acid fomentations followed by a dermatol ointment or iodoforn and benzoin. Sulphonamides were tried without much success, but penicillin was more satisfactory in a few cases. The article has some excellent photographs showing the natural condition and that seen in the inoculated volunteers.

H. Harold Seid

MISCELLANEOUS DISEASES

ALKAN W. J. One Year of Military Medicine in the Central Mediterranean Area. *Acta Med. Orientalia*. 1948 Apr. 7 No 4 76-82.

This is a review of 3,831 patients treated in hospital from July 1945 to June 1946 of whom 1,657 were in two hospitals in Italy (1945) and 2,195 in Greece

(1946). Fifty per cent of these suffered from infectious diseases, all, with the exception of about 250 prisoners-of-war, being young and healthy men. The most interesting groups of cases are described in detail.

The distribution was as follows —

| Malaria | Italy | Greece | Total |
|-----------------------------|-------|--------|-------|
| Benign tertian (primary) | 29 | 18 | 47 |
| Benign tertian (relapse) | 77 | 9 | 86 |
| Malignant tertian (primary) | 3 | — | 3 |
| Malignant tertian (relapse) | 1 | — | 1 |
| Clinical malaria | 3 | 2 | 5 |
| Total | 113 | 29 | 142 |

The low incidence of malaria is thought to have been due mainly to suppressive administration of mepacrine. *Plasmodium vivax* infections, as compared with those caused by *Plasmodium falciparum*, appeared to show relapses in a larger proportion of cases after the drug was discontinued, but some of the so-called relapses were probably re-infections. Every effort was made to diagnose cases microscopically before beginning treatment.

Bacillary dysentery This was commoner in Greece, the disease being always of a mild type. There were 103 cases. Sulphaguanidine appeared to shorten the illness.

Amoebiasis The figure of 67 cases is considered to be too low, as it was found to be impossible in practice to re-examine microscopically every diarrhoea stool, but the need for the most careful investigation of all patients where this infection is suspected is stressed, and sigmoidoscopy was done on all the cases of amoebiasis before discharge. It was found that fresh cases intensively treated from the beginning showed comparatively fewer relapses than the more chronic ones.

Enteric fever Six cases were seen, this is striking evidence of the efficiency and thoroughness of preventive inoculation with T A B vaccine.

Miscellaneous infectious diseases There were 1,390 cases, the most common were infective hepatitis and "short-term" fevers. The former (240 cases) was usually a mild infection and a number of cases of hepatitis without jaundice were seen. These patients were given a diet low in fat, rich in proteins and carbohydrates, with a minimum of roughage. Of the short-term fevers (472 cases) a large number were typical sandfly fever and only 1 case of dengue was seen. Of 554 cases of respiratory affections, the most interesting group was primary atypical pneumonia (149 instances). There were 106 patients with pulmonary tuberculosis, 43 being prisoners-of-war.

Warnings were given against the use of sulphonamides in eczematous conditions. Psychosomatic disorders (gastro-intestinal, respiratory, cardiovascular and urogenital) accounted for 71, and pure psychoneuroses for 121 cases. Sixty-eight patients were admitted without any definite illness being found, but there appeared to be no definite evidence which would label these as malingers.

C. F. Shelton

DAVIES J N P. Pathology of Central African Natives. Malaga Hospital Post Mortem Studies—VII. *East African Med. J.* 1948 June v 25 No. 6, 228-35. [20 refs.]

This series which is concerned with causes of death in African children consisted of 164 children under the age of 10 years divided into three groups according to the usual convention.

Group I—Neonates, 28 children under the age of 28 days. The most common single cause of death was infection, mainly pneumococcal. In none of the cases was evidence of syphilis found, nor is malaria reported as a cause of death.

Group II—Infant under the age of 12 months. This group consisted of 48 children. Malaria was a cause of death in only 8 cases. As a direct cause of death it does not appear to be of significance though it may act indirectly by undermining resistance. Only one case of syphilis was observed. Again, infection particularly pneumococcal, was the most common cause of death. Of 8 cases of purulent meningitis four resulted from the pneumococcus. Most of the children showed evidence of malnutrition but in only 3 was it marked and considered a cause of death.

Group III—Children from 1 to 10 years. This group contained 100 children and in them multiple disease manifestations occurred rendering it difficult to determine the exact cause of death. Infection, malnutrition and malaria were often associated.

Malnutrition lay at the background of most cases. Nearly every African infant shows signs of a fine monolobular cirrhosis with portal cell accumulation. This suggests that nearly every African child goes through a kwashiorkor phase. The importance of malaria as a cause of death was slight. Infection were responsible for the greatest number of deaths, the pneumococcus being the chief offender and the tubercle bacillus a close second. There seems to be no distinction between childhood and adult tuberculosis in Uganda; all cases seem to show the characteristics of primary infections. Of tropical diseases there were only 9 cases of malaria, 2 of amoebiasis and 6 of plague. Five cases of neoplasm and one of malignant hypertension were noted. Syphilis does not appear in the list of findings and a feature was the unimportance of helminthic infections.

[The paediatrician in Kampala would find that his problem did not lie in the field of tropical medicine but in the cosmopolitan diseases of childhood.]

P. I. Clark

MILAR J C. A Brief Review of Fifty Years of Medical History in Selangor Federation of Malaya. *Med. J. Malay.* 1948 Mar v 2, No. 3 161-73.

This is an interesting piece of Colonial history compiled, one presumes, from official reports. It cannot satisfactorily be summarized. The author deals with his subject under various heads: hospitals, health legislation, dangerous infectious diseases, prevailing diseases, beriberi, fever and malaria, dysentery and diarrhoea, influenza and enteric fever.

In a table are given the number of cases of smallpox, typhoid, plague, beriberi, dysentery, diarrhoea and fevers reported each year from 1891 to 1939. The only one of these to show steady reduction is beriberi which began to decline from figures over 2,000 per annum before the 1914-18 war to 69-444 per annum from 1938 to 1939. Plague was never common and neither cholera nor amebiasis was responsible for large numbers of cases.

The author does not give any systematic account of the outstanding investigations made during the period, but rather just updates the well-known comment: servants' manual or lay in their reports. Charles H. Smith

CASIS SACRE, G Impresiones parasitológicas a través del Seguro Social Mexicano [Parasitism in Mexico] *Medicina Mexico* 1948, July 25, v 28, No 560 318-24

The staff of the Social Security Service in Mexico has been inquiring into the existence and prevalence of parasitic infections in the State. The general conclusions are that intestinal parasites are much more common among the poorer and uneducated classes of society and that, in order of importance, these parasites (and infections) are *Enterobius vermicularis*, *Ascaris lumbricoides*, *Taenia saginata*, *T. solium* and *H. nana*, amoebiasis and giardiasis. Malaria, *Trichuris* infection and uncinariasis cases are comparatively few and usually imported.

Enterobius vermicularis is the commonest infestation, in Mexico City 80 per cent of the parasitism is by this worm and it is specially common among those living in poor and insanitary conditions and among the larger families. Treatment by gentian violet, in courses of 8 days with a week's interval, proves satisfactory. *Ascaris lumbricoides* is very common also, again among the poor living in insanitary conditions. It is found even in children less than a year old. Hexylresorcinol is the usual drug for treatment, or, if the children will not swallow this, santonin and chenopodium in castor oil. *Taenia saginata* is more frequently met with than *T. solium*, especially in the Federal District. Cases are probably more numerous than is supposed because patients do not come for treatment unless they see the proglottides themselves, and there exists the peculiar belief that expulsion of the worm as the result of medical treatment is followed by serious after-effects, perhaps even death of the patient, they prefer to keep their worms year after year. *Hymenolepis nana* is seen, almost exclusively in children. Filix mas is not used in treatment "in spite of its being recommended in the books because, if this medicament is dangerous for adults, it must be more dangerous for children". The author gives atebryn instead.

Intestinal amoebiasis has been reported as infecting 5 per cent of 105 school-children in a residential part of the capital and in 34 per cent of the inmates of a Children's Home (alumnos de un internado) in the suburbs. How much of this is due to *E. histolytica* is doubtful because, as the author naïvely states the technical microscopists find it difficult to distinguish *E. histolytica* from *E. coli*. In view of possible liver abscess or other complication, efforts will be made to render the diagnosis more certain and to determine the actual prevalence by examining the faeces of large numbers of the people, by routine examination of the faeces of all patients complaining of diarrhoea or dysentery and "by selecting microscopists whose findings can be received with confidence". Giardiasis is reported as present in 10-20 per cent in Mexico City, atebryn is used in treatment. Malaria is mostly associated with *P. vivax* and is more common than is generally reported because most people regard it lightly and treat themselves, on the other hand, anyone with fever particularly if it is rhythmic (periodic) takes quinine or atebryn or plasmoquine without calling in a doctor, or these drugs are prescribed by the doctor without any preliminary blood-examination.

H. Harold Scott

SYMMERS D Splenomegaly. *Arch Pathology* 1948 Mar v 45, No 3 385-409 [37 refs]

A general review

DANARAJ, T J Eosinophilic Lung *Med J Malaya* 1947 June, v 1 No 4, 278-88 2 graphs [18 refs]

Eight cases of this condition are described, the patients being four Ceylonese, three Indians, and one Chinese, all males except one. Symptoms consisted of

1. breathlessness and cough, sputum being sometimes purulent and occasionally blood-stained. Six of the patients complained of loss of weight and in one a Ceylonese schoolboy this was the only presenting symptom. The authors found the most troublesome complaint to be a paroxysmal cough which was always worst at night.

On clinical examination rhonchi were heard scattered throughout both lung fields in five cases, the lungs being clear in the other three. X-ray examination showed characteristic mottling of both lungs in four cases and of one lung in one case. Another showed increased vascular markings, while in two the lungs were clear. Sputum was examined for tubercle bacilli and mites but none were found. The technique used for searching for mites is not described. A marked eosinophilia was found in all cases, the highest count recorded being 33,264 eosinophils per cmm.

Treatment consisted of arsenic, given in the form of nearsphenamine six injections of 0.3 gm. in six cases and stovarsol 4 grains t.i.d. for seven and ten days respectively in the other two. Four of the patients were cured, three were improved, while one was showing a favourable response although treatment had not been completed.

The author emphasizes the importance of performing repeated blood counts in order to avoid missing this condition. Out of the eight cases which he describes, one had been wrongly diagnosed as pulmonary tuberculosis and three as bronchial asthma. One of the latter had an initial eosinophil count of 4,097 which rose to 17,700 three weeks later.

PROTOZOOLOGY GENERAL

TALLAFERRO W. H. The Inhibition of Reproduction of Parasites by Immune Factors. *Bact. Reviews*. 1948, Mar. v. 12, No. 1 1-17 2 figs. 68 r (s.)

This interesting paper is an exposition of certain new regarding the mechanisms restricting unlimited reproduction in parasites and the part played by them in immunity. Much of the most important work on this subject has been carried out by the author and his summary here of this and of the studies of other in the same field make a very useful contribution to the subject.

It is not possible in a short review adequately to summarize the content of the paper and those interested in the subject must consult the original. But a brief account of the salient points will indicate the scope of the work.

Inhibition or impairment of reproduction in parasites brought about by immunity mechanisms must, in the last resort, depend on the effect of the latter in impairing the metabolism of the parasites

This inhibition of reproduction can be recognized in three forms. The first is exhibited in the case of certain nematodes. Here the immunity mechanism produces its inhibitory effect on reproduction merely as part of a general depression of the metabolic processes of the parasite, but without specific action against reproduction.

In the next form, the immune reaction exercises the same unspecific generalized inhibitory effect on metabolism, including that on reproduction but, in addition, is reinforced by physiological disorganization in the host itself, caused by toxins produced as a result of antigen-antibody reactions. Of this nature is the sum of the immunity responses in malaria.

In the third form, there is a demonstrable and special retarding effect on reproduction, so specific that it leaves the remaining normal metabolic activities of the parasite practically unaffected. This type of inhibition of reproduction is seen in certain non-pathogenic trypanosomes such as *T. lewisi*. The specific antibody producing this effect was described by the author in 1924 and later named "ablastin". It has been the subject of research by a number of investigators.

H E Shortt

VAN CREVELD, S, ARONS, P & DE BRUYNE, J I. Toxoplasmosis gecombineerd met situs inversus totalis [Toxoplasmosis in a Patient with Situs Inversus] *Nederl Tijdschr v Geneesk* 1948, Sept 18, v 92 (III), No 38, 2903-9, 5 figs (4 on pl)

The English summary appended to the paper is as follows —

"Description of a case of congenital toxoplasmosis in a girl with complete situs inversus. The diagnosis of toxoplasmosis was founded besides on the presence of characteristic clinical symptoms, on the result of serological reactions. A sister of this girl, born 15 months after our patient, is now 8 months old and till yet shows neither clinical symptoms nor serological reactions of toxoplasmosis."

ENTOMOLOGY AND INSECTICIDES GENERAL

JAMES, M T. The Flies that cause Myiasis in Man. *U S Dept of Agric Wash Misc Publication No 631* 1947, Sept, 175 pp, 98 figs [160 refs]

This publication provides a general review of the subject of myiasis in man, followed by a systematic consideration of the species of flies involved. It is an extremely valuable general account of the subject.

In the first thirty pages, the author discusses the classification of myiasis, a rather amorphous subject. Patton, as will be remembered, grouped his insects into those of which the larvae are specific and obligate parasites of man (or other vertebrate), secondly those which are semi-specific (normally breeding in dead material but occasionally living in diseased tissues on a living host), and thirdly those of which the larvae occur accidentally in the gastro-intestinal tract (or other passages). Bishopp and others on the other hand have adopted a classification based on the organ or tissue affected. This suits the surgeon, but the entomologist rightly objects, because a particular insect may parasitize several organs and appear in several places in the classification. In the present work, the author uses a rather full classification based on site and organs, but sets out most of his data under genera and species. His general discussion of

types of myiasis i full and shuable It is under such headings as traumatic myiasis myiasis of nose mouth, etc. anal myiasis and so forth.

The general part of the work contains enough entomology to make the publication self-contained there are condensed accounts of the anatomy of the adult and larva of the Diptera, followed by keys which deal only with those forms which may cause myiasis. There are also notes on rearing maggots on synthetic media, and on other matters of technique.

The bulk of the paper some 130 pages deals with these insects in a taxonomic way Where necessary keys to genera and species are provided, and there are many illustrations of flies, maggots and details of anatomy Under each species the author gives the characters by which it may be recognized, the geographical distribution (in considerable detail) life history, pathological importance and a few selected references to literature The author is critical of many published records. He includes a brief consideration of certain species which are known veterinary significance and which might infest man. In this section there is an immense amount of information.

The author is to be congratulated on having been selective and on his brevity But it is to be regretted that he completely passes over the interesting and important work carried out at Freetown on "metazoan immunity against larvae of *Cordylobes*" A section on the treatment of myiasis (which may be a most urgent matter and which is neglected in standard text book) should have been included.

COLAS-BELCOUR, J. & MILLOT, J. Contribution à l'étude des tiques de Madagascar Sur une variété nouvelle de *Hemaphysalis* hôte l'homme humain par *Ba. papill.* The Ixodid Ticks of Madagascar A New Variety of *H. kooli*. Parasitism of Man by a Species of *Hemaphysalis*. *Bull. Soc. Path. Exot.*, 1948, 41, Nos. 5 & 334-8, 2 figs.

BRUMPT, E. & CHARRAUD, A. G. L'infestation par des tiques provoque-t-elle une immunité chez l'hôte? I Note préliminaire Does Infestation by Ixodid Ticks provoke Immunity? (*Ann. Parasit. Humaine et Comparée*, 1947 1 22, Nos. 3 & 343-53).

The authors describe a number of experiments with various animals in an attempt to determine whether an infestation with tick larvae produced acquired immunity in the animals which prevented subsequent batches of tick larvae from engorging.

The accumulated data are tabulated and the results discussed. From these it is concluded that the phenomenon is not a general one and that no immunity is induced in the rabbit by either *Hyalomma excavatum* or by *H. deforme*. This may be true also in the case of *Amblyomma sanguinum* and *H. lewis* and the dog, but the results are not conclusive. The authors are prepared to admit

provisionally that in one experiment *Dermacentor pictus* induced an immunity in the rabbit, but there was no cross immunity when *Hyalomma detritum* was used

H S Leeson

CULPEPPER, G H Rearing and Maintaining a Laboratory Colony of Body Lice on Rabbits *Amer J Trop Med* 1948, May, v 28, No 3, 499-504, 1 fig

A review of the literature indicates that the body louse (*Pediculus humanus corporis*) has not been successfully reared for more than two generations without results obtained in the successful rearing of 25 generations of body lice on certain domesticated rabbits

The lice were kept at 85°C (29 4°C) and 60 per cent RH in beakers and Petri dishes, on patches of blue or black woollen cloth approximately 1½ inches square The patches were transferred to the bare skin of the rabbits, placed on their backs in specially designed stanchions A photograph illustrates how the rabbits are held Two feeds a day are sufficient, 1,600 to 4,000 lice can be fed at one time A colony of 40,000 lice is being maintained on sixteen rabbits, four being used each day

In initial tests only four out of twenty-five rabbits were found to be favourable hosts, later seven out of ninety-seven were favourable On favourable rabbits the lice feed to repletion in 12 to 20 minutes, whereas on unfavourable animals the lice attach more slowly and take up to 30 minutes for repletion By transferring lice of the tenth generation from favourable to unfavourable rabbits a strain was built up which was sufficiently adapted to the unfavourable rabbit to produce a satisfactorily vigorous colony Lice have been carried through fifteen generations, on unfavourable rabbits, after ten on favourable ones

Data are given which show that egg production and longevity of rabbit-bred lice compare well with those of lice reared on man, and lice from naturally infested men can be reared on favourable rabbits just as successfully as those from the laboratory colony There was no difference in susceptibility to pyrethrum and DDT between lice reared on man and those reared on rabbits

BARRY G T & BOYER R The Synthesis and Biological Toxicities of some DDT Homologues and related Compounds *Canadian J Res Sect B Chem Sci* 1948 July v 26 No 7 511-17 [14 refs]

VARGAS, L Fototropismo positivo en larvas de mosquito intoxicadas con DDT. [Positive Phototropism in Mosquito Larvae Poisoned by DDT] *Rev Inst Salubridad y Enfermedades Trop Mexico* 1948, Mar, v 9, No 1, 47-9.

The English summary appended to the paper is as follows —
"Mosquitoes *Aedes* and *Anopheles* show in the adult stage, during the excitation period produced by the poisoning with DDT a strong positive phototropism The same phenomena can be observed in larvae of *Aedes aegypti* and *Anopheles pseudopunctipennis typicus*"

ENICK, K Die Wirkung neuartiger Insektizide auf Milben I Mitteilung Laboratoriumsversuche [The Effect of the Newer Insecticides on Ticks and Mites] Reprinted from *Deut Tierärztl Woch* 1948; v 55, Nos 5/6 & 7/8, 40-43 51-6

The author reviews our knowledge of the effect of the newer synthetic insecticides upon ticks and mites (Acarina) and describes his own experiments

In his own work the author used a number of substances which are referred to under proprietary names. In nearly all cases the formula of the actual insecticide is quoted, but the methods of compounding (which may so greatly influence the efficacy of the insecticide) are withheld. The insecticides included DDT a xanthogen, hexachlorocyclobexane p-chlorophenylchloromethylsulphone and others also simpler materials e.g. sodium arsenate phenol etc. The test animals were *Ornithodoros* *Ixodes* *Dermawynus* and *Psoroptes* (causing mange in rabbits). They were exposed for stated periods on impregnated filter paper but the experimental methods are not fully explained and the dose of material per unit area of paper is not ascertainable.

The results are tabulated, but are difficult to summarize. One observes the great resistance of *O. moubata* to many materials (as already recorded by ROBINSON this Bulletin 1944 v 41 97") it is however relatively quickly killed by hexachlorocyclobexane and E 803 I (diethyl-p-nitrophenyl-monothiophosphate) the latter is remarkably effective against several other Acarina, but is dangerous to mammals.

LABORATORY PROCEDURES

MAXWELL, R. D & FRIGELSON P. A Modified Method of preparing the J.S.B. Stain. J. Lab. & Clin. Med. 1943, June, v 33, No. 6, 777-82, 1 fig. [11 refs.]

A slight modification in the preparation of the polychrome methylene blue of J.S.B. stain is shown to be advantageous. The original method of autoclaving the solution and adding potash to the resultant fluid did not always give constant results. Instead, the mixture of 0.5 gm. of medicinal methylene blue 0.5 gm. of potassium dichromate and 3 cc. of 1 per cent. sulphuric acid in 500 cc. of water is heated for three hours in a boiling water bath and the precipitate is removed by filtration. It is dissolved in 500 cc. of M/20 disodium hydrogen phosphate and the solution is allowed to mature for 48 hours before use. It keeps well for months, but if required the precipitate may be dried in a vacuum desiccator and dissolved when necessary in the phosphate solution (0.1 per cent. of stain).

It was discovered by spectrophotometric methods that the polychrome methylene blue consisted of a mixture of about 25 per cent. methylene blue and 75 per cent. azure blue. An artificial mixture of these was found to stain nearly as well as the natural product. [The authors use a very acid wash water (buffered at pH 6.7). A more alkaline water (about 7.2) is better if stripping of the red blood cell is to be demonstrated.]

REPORTS SURVEYS AND MISCELLANEOUS PAPERS

CHRONICLE WORLD HEALTH ORGANIZATION 1943 July v 2, No. 7 137-48
The International Control of Cholera, Smallpox and Plague. A Note on the First Session of the Expert Committee on International Epidemic Control and the Three Joint OHP-WHO Study Groups on the Pestilential Diseases.

The Interim Commission of the World Health Organization set up an Expert Committee on International Epidemic Control "to examine the circumstances

underlying the spread of the major epidemic diseases and to restate the principles which should serve as a basis for their international control" The first session of this Committee in April was preceded by a meeting of three study groups of experts in Paris, set up jointly by WHO and the *Office International d'Hygiène Publique* the groups made observations on recently established facts to be considered in the drafting of new international sanitary regulations

The first group, which dealt with *cholera*, defined "medical examination" as including such laboratory examinations (e.g., rectal swabbing) as are deemed necessary by health authorities They recognized anti-*cholera* vaccination as of definite value but, in view of the relative character of the protection afforded, they felt that vaccinated persons should not be exempted from all control measures They considered immunity to be manifest as early as the fourth day after injection, reaching its maximum on the eighth day and lasting at least six months A single injection of 1 ml of vaccine confers an appreciable immunity and constitutes a proper procedure for mass-vaccination campaigns Two injections at a week's interval are preferable and should be given to those particularly exposed There is no contraindication, as *cholera* vaccination gives little or no reaction, it can be applied to all ages provided care is taken in the case of infants to reduce the dose in proportion to body weight The group also discussed the antigenic potency of the mixed strains used at present and the transformation from "smooth" to "rough" forms during the course of the disease and convalescence The WHO Expert Committee on Biological Standardization will consider these observations in arriving at a definition of a universally acceptable vaccine

The second group discussed *smallpox*, under the headings of the pathogenic agent, modes of transmission and vaccination They recommended new studies on egg media of the agents responsible for mild and malignant forms, which appear to be identical but have not yet been conclusively proved to be so RNET's work in Melbourne on the estimation of immunity was considered essentially valuable and should be repeated On transmission, the group felt that all the possibilities had not been explored and recommended studies on the existence of the virus in bucco-pharyngeal droplets They reaffirmed the fourteen-day quarantine period as laid down in the Conventions Vaccination still remains the outstanding measure of defence The group recognized the superiority of calf lymph and preferred Leake's multiple pressure technique The danger of post-vaccinal encephalitis for a community is not to be compared to that of *smallpox* in the absence of vaccination The best way to avoid this complication was to carry out primary vaccination well before school age Babies should be vaccinated between the third and sixth months In the case of an epidemic, all children, irrespective of age, should be vaccinated

Of great importance are the definitions suggested for the reactions observed after re-vaccination In addition to the successful and accelerated reactions, they define the so-called immunity reaction, for which they prefer the term "precocious non-vesicular" as "characterized by the appearance after the first day, of a vaccinal lesion which does not develop beyond the papulo-macular stage, is pruriginous and disappears at the latest on the third day" It is in reality the expression of an antigen-antibody reaction which does not necessarily imply that it is accompanied by immunity They also recommended that all vaccination certificates which did not record a success or an accelerated reaction should be considered valid for six months only, while a doctor's statement confirming that he had observed a reaction of either kind should be valid for three years at least (The Expert Committee considered that it was impossible to adopt this fundamental change of principle without further study, and deferred a decision)

The group on *plague and other diseases* recommended residual insecticides such as DDT as the chief measure of international protection against plague. The combined use of the new rodent poisons and insecticides should eradicate plague from ports, towns and villages but was not of course effective against zoonotic enzootics. It was recognized that the incubation period, particularly in mild and vaccinated cases, might exceed the six days recognized by the conventions but the new insecticides and the curative action of sulphonamides and streptomycin diminish the chances of secondary contamination of ectoparasites and thus lessen the importance of the length of the incubation period. The incubation period of typhus was considered for practical purposes to be fourteen days rather than the Conventional twelve days. The use of residual insecticides is the essential measure for international protection, as in plague but disinfection as well as disinsection of the fomites was recommended in view of the danger of contamination by lice and flea excreta.

The Expert Committee on International Epidemic Control itself considered all these observations and in addition, recommended (1) a delimitation of the endemic zones of pestilential diseases as a first step towards an attack on endemic foci—the best method of all (2) improvements in the present system of notifying urgent information particularly by broadcasting (3) the inclusion of louse-borne relapsing fever among the pestilential diseases and (4) the inclusion of cerebro-spinal meningitis, dengue fever, epidemic influenza and poliomyelitis among the diseases for which immediate notification of epidemics must be made.

[Apart from the elimination of endemic areas, the procedures for international protection against epidemics—still known collectively as "quarantine" though quarantine as such now plays but a minor rôle—fall into three stages. First, to collate and agree on the scientific measures required in the light of the most recent knowledge. Second, to translate these requirements into acceptable administrative measures. Third, to put such agreed administrative measures into force by international and national legislative action. The study groups referred to above represent the first of these processes, the Committee on Epidemic Control represents the second, and the third will be the adoption in due course of international regulations by the World Health Assembly in place of the existing Conventions, and their implementation by States members of the World Health Organization.]

WASHINGTON. DEPARTMENT OF STATE. Fourth International Congress on Tropical Medicine and Malaria. Abstracts. 1948. May 10-18. pp. iv + 148. Washington D.C.

In the past there have been two distinct series of International Congresses of direct concern to tropical medicine—that on Malaria, and that on Tropical Medicine. Both of these had their own permanent machinery which provided among other business for the calling of Congresses at regular intervals but as a result of the war the machinery of both broke down and they were in danger of permanently lapsing. The President of the United States took the initiative of re-assembling, both on his own authority, at a joint meeting under the title of the Fourth International Congress on Tropical Medicine and Malaria, held in Washington from 10th to 18th May 1948. In doing this, the United States Government has been of the greatest service to the science of tropical medicine, a service enlarged and underlined by the Honorable George G. C. Marshall, Secretary of State in an opening address which stressed the concern of his Government to co-operate with others in the promotion of public health in the tropics.

About sixteen hundred persons took part, representative of all countries with interests in the tropics or subtropics, except the U.S.S.R. The machinery of the Congresses was re-established, and a proposal was agreed that the two Congresses should in future be amalgamated in one, though the programme arrangements should be adjusted under two Vice-Presidents in harmony with the predominant interest in malaria. The future of these Congresses is thus assured.

The volume under review is a series of abstracts of papers, mostly unsuited to further abstraction. Their general scope is indicated by the Section titles: Research and Teaching Institutes, Tropical Climatology and Physiology, Bacterial and Spirochaetal Diseases, Virus and Rickettsial Diseases, Malaria, Helminthic Diseases, Protozoan Diseases, Nutritional Diseases in the Tropics, Tropical Dermatology and Mycology, Tropical Veterinary Medicine, Public Health, and Medical and Veterinary Entomology.

Any attempt to assess the relative interest and value of some 170 papers must inevitably largely reflect the interests of the majority lay. Without doubt the place at meetings of the section on malaria, incomparably larger than that at any other, showed where the interest of the writer. However, the attending paper and demonstration by H. E. SHORTT on the pre-erythrocytic cycle of *Plasmodium cynomolgi* with the impromptu inclusion of that of *P. vivax*, were of an outstanding importance, recognized by the award to him of the Laveran Prize. The presentation of evidence on the qualities of new drugs, chloroquine, pentaquine, isopentaquine and paludrine, brought out particularly the efficacy of pentaquine in preventing relapses of *P. vivax* (the relapse rate of the intractable Southwest Pacific [Chesson] strain was reduced from 98 per cent to 25 per cent by a single therapeutic course in combination with quinine, and to 2 per cent by two courses) the probable but as yet unverified superiority of isopentaquine, the toxicity of pentaquine which makes it unsuitable for indiscriminate use in full doses without close medical supervision, and the position of paludrine and chloroquine as prophylactics. The general impression gained was that chemotherapeutic research has produced two almost perfect prophylactics or suppressants against *P. falciparum*, and the progress made indicates that the problem of relapsing *P. vivax* infections will eventually be overcome entirely.

Discussion on the control of malaria centred round two main objects, attempts at total eradication of anopheline species and attempts at permanent but constantly recurring control short of eradication by the use of residual insecticides. F. L. SOPER read an important and imaginative paper which brought together information on past schemes for the eradication of *Aedes* and *Anopheles* and from this tried to forecast the possibilities of future work. Briefly, he considers that it is possible to eradicate any species of mosquito which is entirely domestic in its habits, but that the attack on forest-loving species is impossible on their own ground. Thus and other papers gave together a composite picture of widespread application of the two principles which was a revelation to the reviewer. The picture includes the extinction of *Aedes aegypti* from a considerable proportion of the South American continent, eradication or perfect control of anopheline vectors of malaria throughout the whole of Chile, Peru, Venezuela, British Guiana, Italy, Greece, Cyprus, and from large areas of Bombay Province, the virtual though not yet absolute ending of malaria in the United States, and a number of schemes each more ambitious than would have been thought possible ten years ago. The assembly of knowledge on this subject, with opportunities for formal and informal discussion between those concerned would alone have been adequate justification for the Congresses.

Another outstanding feature was the discussion on the use of chloromycetin against rickettsiae, and particularly the account of its use in the treatment of

scrub typhus in Malaya, which clearly showed that the typhus group of fevers can no longer be considered resistant to treatment. The sessions on helminthic diseases were notable for the discussions of the place of Mebexan in the treatment of bilharzia. Many American veterans have returned from the war with infections with *Haemeria bancrofti* which are either symptomless or mainly productive of anxiety states, and this drug has shown marked success as measured by the disappearance of microfilariae from the blood. It was however a matter of common comment that the resultant death of the parent worm often gave rise to a symptom complex which appeared to the patient to represent an exacerbation of the disease. There was much of interest in the Section concerned with Virus Diseases. This was not confined to tropical infections, concerning itself considerably with infectious hepatitis and transfusion jaundice on which some valuable data of direct concern to the surgeon were presented but the discussions dealt at considerable length with tropical poliomyelitis, yellow fever and other diseases. Poliomyelitis has only recently been recognized as a specific tropical problem, but the work presented at the Congresses should firmly establish its place as such. R. M. TAYLOR and MAX THILLEN gave an authoritative statement on the epidemiology of yellow fever which included all the recent work on jungle virus and its transmission, and MAURICE PELTIER gave a useful account of the Dakar yellow fever vaccine which is administered by scarification and has now been given to over five million people. The vaccine is approved by UNRRA and its successor WHO.

The many other subjects discussed ranged over very wide fields. The reviewer was specially interested in a paper on Population Problems in the Tropics by T. LYNN SMITH. In papers by G. GIRARD and K. F. MEYER on the place of live vaccines in the prophylaxis of plague. In one by S. S. VORNEY and P. M. WAGLE on the treatment of plague, which showed that streptomycin is outstanding (3.3 per cent. mortality in all cases, 10.7 per cent. in cases which were septicaemic at the start of treatment) and sulphadiazine of great value (4.2 per cent. and 18.1 per cent. in comparable series) and in a paper by C. G. PAYNTE on cholera vaccines. Other readers would, however inevitably select other papers as of special concern, and no one could participate in the Congresses without feeling that almost all branches of tropical medicine were enriched both by papers and by formal and informal discussion.

The volume under review consists of about 170 authors abstracts of all varying length and detail, study of which gives little indication of the relative value of the papers. It was useful in arranging one's daily programme at the Congresses and will be of use for record purposes. The reader interested in the substance of papers is advised to wait the publication of the Proceedings which may not be long delayed.

G. Macdonald

THOMSON W. A. R. *African Medicine. Practitioner* 1948, Sept. & 1949 No. 963 215-10

In this short paper which records impressions made during a tour from Cairo to the Cape in the space of two months the author makes a few pertinent observations, the first of which is that in Africa, men and money have never been available to allow of systematic surveys of disease such as are now considered essential in any well-run state. Hospital records are inevitably unreliable and the true incidence of disease can only be assessed by survey work. (This observation, no doubt is true but surveys have been made in Africa, sometimes on a large scale though more are needed.) The second is that little is known of the nutritional status and physiology of the "normal" African.

The author refers to overcrowding in hospitals and to the fact that in most medical laboratories there is so much routine work to be done that the opportunities for research hardly exist. He mentions malaria, sleeping sickness, schistosomiasis, amoebiasis, tuberculosis and leprosy as diseases of major importance, and ends by pointing out the valuable work done by members of the Colonial Medical Service

Charles Wilcocks

LEITE, A S, DA LUZ, J V B & DE MEIRA, M T V. Relatório da Missão Médica do Instituto de Medicina Tropical a Angola em 1945 [Report of the Medical Mission of the Angola Institute of Tropical Medicine, 1945] *An Inst Med Trop* Lisbon 1947, Dec, v 4, 465-500, numerous figs on 33 pls (1 coloured) & 1 folding map

The object of this mission was twofold. To verify the presence of dermatomycoses in the Luanda-Malanga region, between Benguela and the Belgian Congo, and, if possible, in the Zaire basin, secondly, to collect material for study and demonstration at the Institute. A sketch map indicates the route taken, by ship, aeroplane and automobile.

The authors found that superficial mycoses were common—pityriasis versicolor, tinea, epidermophytoses at times severe like tokelau (*Tinea imbricata*), favus, infections by *Trichophyton ferrugineum* (a very fine coloured plate depicts the growth of this on Sabouraud glucose) and other trichophyta, and sporotrichosis.

As regards the second objective, the usual collection was made of helminths, especially schistosomes and their vectors, larval and adult forms of diptera, blood specimens for trypanosomes, microfilariae and spirochaetes. Records are given of cases of leprosy, keloid, gangosa, yaws, late syphilis with mutilations, ulcers, onchocerciasis, etc. The whole account is well illustrated with photographs of the mission and its equipment, very realistic reproductions of favus and sporotrichosis, keloid and fungus affections of the feet.

H Harold Scott

HEISCH, R B. A Survey at Garsen. *East African Med J* 1948, May, v 25, No 5, 220-24, 1 map

Garsen is on the Tana River in Kenya, not far from the coast, and was a possible accessory site for the East African groundnuts scheme. A parasitological survey of the indigenous inhabitants was made in 1947. The malaria parasite rate in children was 53 per cent, in adults 9 per cent, the species being predominantly *P falciparum*, though three infections with *P malariae* were observed. Nomadic tribes (Galla) showed a high spleen rate (34 per cent), a condition attributed to poor immunity. Night blood films were examined for microfilariae and 4 per cent of the non-nomadic people were found to contain them. Faeces contained ancylostome ova (11 per cent), *Ascaris* ova (15 per cent) and *E histolytica* (1.6 per cent). *S haematobium* was frequently seen in the urine (52 cases, but the total examined is not given).

Anopheles gambiae appeared to be the vector of malaria, it occurred in large numbers after the long rains in May. *A funestus* was rare. A tree hole survey revealed the presence of *Aedes aegypti*, *Aedes simpsoni* and *Aedes metallicus*, and various species of the subgenus *Diceromyia*. The commonest and most voracious mosquitoes of the district were *Taeniorhynchus*, one of which (*T africanus*) was found infected with a filaria.

Haemophysalis sp. was found in the blood of local pigeons.

[See also this *Bulletin*, 1948, v 45, 671 for a survey of Taveta by the same author.]

DE MEIRA, M. T. V. NOGUEIRA, J. F. P. & SIMÕES, T. S. Relatório da Missão de Estudo do Instituto de Medicina Tropical a Cabo Verde em 1946-1947. Report of the Investigations of a Mission of the Institute of Tropical Medicine, Lisbon, to the Cape Verde Islands, 1946-47. *An. Inst. Med. Trop. Lisbon*, 1947 Dec., v. 4 657-711 41 figs. (4 maps)

The Institute of Tropical Medicine, Lisbon, sent out a team, with Dr. Manuel de Meira at the head whose aim was "to carry out studies, clinical, entomological, etc., to acquire knowledge of the pathology of the colony and its characteristic endemic conditions." The same general lines of investigation were followed in the three islands of the archipelago, Sal, Boa Vista and S. Nicolau. The Mission stayed for 7 days in the first-named, 18 in the second and a month in the third. The examinations made and the numbers of persons examined in each of these were small and are not of general interest but one or two points call for remark.

In the island of Sal there was an outbreak of yellow fever in 1873 infection being introduced from Brazil. Some 300 persons were attacked, with a fatality of 51 per cent. Whether it exists now cannot be stated with certainty. If isolated cases do occur they are mild and may pass unperceived among cases of malaria. The determining immunity test has not been carried out. In Boa Vista comparatively few examinations were made. Only 83 were examined for intestinal parasites. 238 were examined clinically and among the only morbid conditions with double figures were diarrhoea, 74 (cause not stated) and chronic bronchitis 18. Noteworthy is the fact that albumin, partial or total, occurred in ten members of a family of 20. In S. Nicolau the number examined was greater. 1,673 specimens of blood were taken for examination later. 294 by day and by night for microfilariae. 10 only for malaria parasites. 494 faecal examinations of 47 persons, by the Willis technique showed *Ascaris* to be the most common infestation among those who had never been away from the island and *Trichuris* the next. Hookworm was common in those coming to S. Nicolau from elsewhere especially those recently arrived from S. Thomé. Nineteen cases of tinea were found & due to *Mic. poron felinum*. *Trichophyton ferrugineum* was not found in S. Nicolau. Fungus infections of the feet were far from uncommon. Figures are not given merely the statement *com data* (undivided). Information is given about the mosquitoes found. (See also p. 1122)

H. Harold S. G.

CLARKE, M. C. The Binadins of North Borneo. *Med. J. Malaya*, 1943, Mar., v. 2, No. 3 179-83, 1 map.

The Binadins are sea-going Mohammedans who during the past 60-100 years have spread from the Philippines to some of the islands off North Borneo. They are independent, wild and carefree people who do not work for wages and who do not trade anything but small quantities of fish. They are very poor and live in primitive conditions. During the war they suffered considerably at the hands of the Japanese.

The author gives medical information which he collected on Sulan Island in May 1947. Malaria is common (splen rate 45 per cent) with anaemia only. Few slides could be examined they showed *Plasmodium* only. The chief vector in N. Borneo, *An. kels* *leucophaea* was found also in this island, breeding in the only two existing places in one the water was brackish.

The diet of these people is poor. Fish is an important food, with tapanas and sag but practically no vegetables and little fruit (part from coconut) are eaten and cause a not much needed. Signs of malnutrition are common—dental caries, bleeding gums, as well as stomatitis, magenta tongue, scurvy.

Book Reviews

Vol 45, No 12]

of the skin, depigmentation of the skin Apart from malaria there is not much actual disease, but the poor condition of these people is largely the result of malnutrition, which could be corrected by introducing vegetables and fruit trees, particularly bananas

BOOK REVIEWS

WILLIAMS, Ernest [CMG, CIE, MD, FRCS (Edin), etc] *Manual of Leprosy* pp viii+208, 70 figs (10 coloured) 1948 Edinburgh E & S Livingstone Ltd, 16 & 17 Teviot Place [17s 6d]

This small practical book records the latest conclusions of the author based on his long experience in India and while on tours in Africa and other countries as medical secretary of the British Empire Leprosy Relief Association. It is on similar lines to his manual published some two decades ago in India, but is a new and up to date account written for the guidance of "doctors, nurses and lay workers." It deals mainly with a clinical description of the disease and its treatment and preventive measures now in common use, and makes no pretence to be a complete account of all aspects of the subject. For this reason the history, bacteriology, mode of infection, prevalence and rates of incidence are dismissed in the first seventeen pages, and are followed by short sections on tissue reaction and resistance and the lepromin test. The various recent systems of classification are briefly considered and that of the Pan-American Congress of 1946, based on histological findings, is adopted and summarized in a convenient table under lepromatous, uncharacteristic and tuberculoid types although the difficulties of most workers in leprosy areas in obtaining facilities and time for such histological examinations are recognized by the author.

The next few chapters are devoted to a careful clinical description of this protean disease, which is well illustrated by the author's photographs of cases and of histological changes, a few of which are in colour. This constitutes the most useful section of the book and it includes eye and other complications, bacteriological examinations, differential diagnosis, case taking and prognosis. Thirty pages are next devoted to treatment on the lines advocated by the author, who first recommends the use of injections of hydnocarpus oil and ethyl esters, although in recent years much of the oil supplies to Africa and elsewhere have arrived in a rancid condition unsuitable for this use. The active and convenient sodium hydnocarpate (in the form of alepol) is not mentioned, although its use in Calcutta thirty years ago first demonstrated the value of injections of active preparation of these oils. A chapter on sulphone treatment records the great advances obtained from their use in resistant advanced lepromatous cases by American workers and by the author himself in Trinidad. The recently used sulphethrone is considered to be the most active of these preparations

The last section deals with the method now in use in anti-leprosy control without going into the history of compulsory segregation, which is recommended for the infective cases. The importance of separation of healthy children of infected patients is emphasized. This book can be recommended for the use of workers in the numerous endemic area of leprosy.

L. Higgins

DE SOUZA-ARAÚJO Heraclides-Cesar [Chefe da Secção de Bacteriologia e do Laboratório de Leprologia do Instituto Oswaldo Cruz. História da Leprosia no Brasil. Vol. II. Período Republicano (1889-1948). Album das organizações antileprotas. (History of Leprosy in Brazil.) pp. xx and 380 pls. 1948. Rio de Janeiro: Imprensa Nacional.

This handsome volume depicts the organizations dealing with leprosy in Brazil during the period 1889-1948, the Republican Period. It is the second volume of Professor de Souza Araújo's epochal work on Leprosy in Brazil and truly a monument of industry. The whole is to be completed in 3 volumes. The first was reviewed in this *Bulletin* last year [1947 v. 44 (3)]. This the second volume is an album of photographs with a minimum of letterpress. In addition to portraits of celebrities there are more than a thousand pictures on 380 plates. One cannot in words review a picture gallery: one can only point out the objects aimed at and indicate their importance. True appreciation of their value can only be attained by personal study of them.

There are in Brazil 38 Leprosarias and another under construction in Bahia. Minas Gerais has six. São Paulo five. Pará three and several States have two. The number of patients interned at the end of 1948 totalled 20 638. There are 27 preventoria for children and one more in Acre Territory being constructed. Minas Gerais has four. São Paulo three, others have two or one each, with its Director and Leprologist and 15 of them have a paediatricist also on the staff.

The volume contains portraits of scientists and administrators engaged in leprosy and its prevention and also photographs of various leprosaria, preventoria, plans and patients referring to the last decade of the nineteenth and the first 48 years of the twentieth centuries. In addition, there are group photographs of conferences, congresses and festivals. Each State and the various districts are taken in turn and there are collections of photographs of patients, children and institutions of the highest interest. The original idea was to interpolate these pictures and photographs in the text, dividing them into the three phases into which the "republican period" naturally falls: first to 1920 or the period before modern prophylactic measures were in force; second, the following decade or phase of "Institution for Prophylaxis" by the D.N.S.P. (*Departamento Nacional de Saúde Pública*); the National Department of Public Health; third, the Getulian Period, that is the period of intensification of prophylaxis under the leadership of Dr. Getúlio Vargas 1931-1945. It was however found impossible to carry out this plan of producing text and photographs together and the author has therefore brought out this volume of photographs separately. The letterpress, so far, is to make the third volume which, says the author, is already in an advanced stage.

Professor de Souza Araújo has taken the greatest pains to make the work complete. The reproductions are wonderfully clear and the whole constitutes a collection worth of a place in any library and anyone possessing a copy is indeed to be accounted fortunate. Professor de Souza Araújo is performing a work which will earn him the gratitude of all leprologists and those engaged in the study of the disease and its prevention.

Apart from the intrinsic value of the work itself attention must be drawn to the very generous gesture on the part of the author who is handing over the proceeds of the sale of this volume as he did in the case of the first, to

the International Leprosy Association—an act of philanthropy worthy of the highest honour and gratitude
H Harold Scott

- KEFFER, LUIZA *Índice Bibliográfico da lepra 1500-1943* Vol I A-H [Bibliographic Index of Leprosy] pp xxxviii+1-674 1944
 — *Índice Bibliográfico de lepra 1500-1944* Vol II I-P pp xxi+675-1434 1946
 — *Índice Bibliográfico de lepra 1500-1945* Vol III Q-Z pp xxiv+1435-1936 1948 Biblioteca do Departamento de Profilaxia da Lepra do Estado de São Paulo—Brasil

This monumental work in three volumes and covering over 1,900 pages has been edited by Luiza Keffer, Librarian of the Leprosy Prevention Department of the State of São Paulo, Brazil

It is the fruit of ten years' constant labour in an institution which has collected "one of the greatest specialized bibliographies in medicine, which, at present, has more than 100,000 cards"

Each work mentioned is to be found in the library of the Department and although the Index is restricted to papers contained there, it is stated that it contains "practically everything that has been written about the legendary disease" Indeed this claim would seem to be well-founded, for the references date from the year 1500 to the present day they are arranged alphabetically and there is a comprehensive system of cross references, so that a given work appears under a number of headings

The editor of the Index appeals again to medical workers and editors to send their special publications to the library, where they shall have the widest international publication it is added that the library deals with no less than 185,000 consultations by correspondence annually It is proposed to organize an Annual Supplement to the Index, which will be published as a special number of the *Revista Brasileira de Leprologia*

The worker interested in leprosy and its history could ask for nothing fuller than this tremendous, carefully prepared and well-produced compilation

H J O'D Burke-Gaffney

- CRAIG, Charles Franklin [M D, M A (Hon), D Sc (Hon), F A C S, F A C P, etc] *Laboratory Diagnosis of Protozoan Diseases* 2nd Edition 384 pp, 56 figs & 7 coloured pls 1948 London Henry Kimpton, 25 Bloomsbury Way, W C 1 [27s 6d]

Colonel Craig is one of the leading authorities on tropical medicine in the United States He retired some years ago from active teaching, but returned to fill gaps during the war and has continued to maintain his influence on parasitology in the United States by his contributions to the literature, especially to the literature on parasitological technique

The first edition of this book was published during the recent war and was in great demand amongst medical men in the Forces whose previous experience of parasitology was often very limited The author now feels that, with the many men returning from service who will have tropical infections, especially chronic amoebiasis and malaria, there should be a demand for another edition of his book.

Undoubtedly, Col Craig's long suit is the intestinal protozoa and in particular the amoebae He has made some outstanding contributions to this subject and it is not surprising that he has devoted over two-fifths of the book to amoebiasis and the flagellate infections of the bowel The one hundred and

The last section deals with the method now in use in anti-leprosy control without going into the history of compulsory segregation, which is recommended for the infective cases. The importance of separation of healthy children of infected patients is emphasized. This book can be recommended for the use of workers in the numerous endemic areas of leprosy.

DE SOUZA-ARAÚJO, Heracleides-Cesar (Chefe da Secção de Bacteriologia e do Laboratório de Leprologia do Instituto Oswaldo Cruz) *História da Leprosia no Brasil. Vol. II. Período Republicano (1889-1946). Album das organizações antileprosas.* [History of Leprosy in Brazil.] pp. xx and 330 pls. 1948. Rio de Janeiro: Imprensa Nacional.

This handsome volume depicts the organizations dealing with leprosy in Brazil during the period 1889-1946, the Republican Period. It is the second volume of Professor de Souza-Araújo's epochal work on Leprosy in Brazil and truly a monument of industry. The whole is to be completed in 3 volumes. The first was reviewed in this *Bulletin* last year [1947 v. 41, 760]. This, the second volume, is an album of photographs with a minimum of letterpress. In addition to portraits of celebrities there are more than a thousand pictures on 300 plates. One cannot in words review a picture gallery; one can only point out the objects aimed at and indicate their importance. True appreciation of their value can only be attained by personal study of them.

There are in Brazil 38 Leprosarias and another under construction in Bahia. Minas Gerais has six, São Paulo five, Pará three and several States have two. The number of patients interned at the end of 1946 totalled 20,638. There are 27 preventoria for children and one more in Acre Territory being constructed. Minas Gerais has four, São Paulo three, others have two or one each, with a Director and Leprologist, and 15 of them have a paediatrist also on the staff.

The volume contains portraits of scientists and administrators engaged in leprosy and its prevention and also photographs of various leprosy preventoria, plans and patients referring to the last decade of the nineteenth and the first 46 years of the twentieth centuries. In addition there are group photographs of conferences, congresses and festivals. Each State and the various districts are taken in turn and there are collections of photographs of patients, children and institutions of the highest interest. The original idea was to interpolate these pictures and photographs in the text dividing them into the three phases into which the republican period naturally falls: first the 1920 or the period before modern prophylactic measures were in force; second, the following decade or phase of Intervention for Prophylaxis by the D.V.S.P. (Departamento Nacional de Saúde Pública); the National Department of Public Health; third, the "Getulian Period" that is, the period of intensification of prophylaxis under the governorship of Dr. Getúlio Vargas 1931-1945. It was, however, found impossible to carry out the plan of producing text and photographs together and the author has, therefore, brought out this volume of photographs separately. The letterpress referring to them is to make the third volume which, as the author is already in an advanced stage.

Professor de Souza-Araújo has taken the greatest pains to make the work complete. The reproduction is wonderfully clear and the whole constitutes a collection worthy of a place in any library and anyone possessing a copy is indeed to be accounted fortunate. Professor de Souza-Araújo is performing a work which will earn him the gratitude of all leprologist and those engaged in the study of the disease and its prevention.

Apart from the intrinsic value of the work itself, attention must be drawn to the very generous gesture on the part of the author who is handing over the proceeds of the sale of this volume, as he did in the case of the first, to

the International Leprosy Association—an act of philanthropy worthy of the highest honour and gratitude

- KEFFER, Luiza **Índice Bibliográfico da lepra 1500-1943** Vol I A-H
[Bibliographic Index of Leprosy] pp xxviii+1-674 1944
— **Índice Bibliográfico da lepra 1500-1944** Vol II I-P pp xi+675-1434 1946
— **Índice Bibliográfico da lepra 1500-1945** Vol III Q-Z pp xxiv+1435-1936 1948 Biblioteca do Departamento de Profilaxia da Lepra do Estado de São Paulo—Brasil

This monumental work in three volumes and covering over 1,900 pages has been edited by Luiza Keffer, Librarian of the Leprosy Prevention Department of the State of São Paulo, Brazil

It is the fruit of ten years' constant labour in an institution which has collected "one of the greatest specialized bibliographies in medicine, which, at present, has more than 100,000 cards"

Each work mentioned is to be found in the library of the Department and although the Index is restricted to papers contained there, it is stated that it contains "practically everything that has been written about the legendary disease" Indeed this claim would seem to be well-founded, for the references date from the year 1500 to the present day they are arranged alphabetically and there is a comprehensive system of cross references, so that a given work appears under a number of headings

The editor of the Index appeals again to medical workers and editors to send their special publications to the library, where they shall have the widest international publication. It is added that the library deals with no less than 185,000 consultations by correspondence annually. It is proposed to organize an Annual Supplement to the Index, which will be published as a special number of the *Revista Brasileira de Leptologia*

The worker interested in leprosy and its history could ask for nothing fuller than this tremendous, carefully prepared and well-produced compilation

- CRAIG, Charles Franklin [M D, M A (Hon), D Sc (Hon), F A C S, F A C P, etc] **Laboratory Diagnosis of Protozoan Diseases** 2nd Edition 384 pp, 56 figs & 7 coloured pls 1948 London Henry Kimpton, 25 Bloomsbury Way, W C 1 [27s 6d]

Colonel Craig is one of the leading authorities on tropical medicine in the United States. He retired some years ago from active teaching, but returned to fill gaps during the war and has continued to maintain his influence on parasitology in the United States by his contributions to the literature, especially to the literature on parasitological technique

The first edition of this book was published during the recent war and was in great demand amongst medical men in the Forces whose previous experience of parasitology was often very limited. The author now feels that, with the many men returning from service who will have tropical infections, especially chronic amoebiasis and malaria, there should be a demand for another edition of his book.

Undoubtedly, Col Craig's long suit is the intestinal protozoa and in particular the amoebae. He has made some outstanding contributions to this subject and it is not surprising that he has devoted over two-fifths of the book to amoebiasis and the flagellate infections of the bowel. The one hundred and

forty-five pages on the subject give much more than the student will require and constitute a valuable source of reference for the advanced worker since for example he has given about 20 different media and methods of cultivation of *Entamoeba histolytica*. Three methods of his own are included. He naturally prefers his own methods but in summarizing this subject he says that it is better to persevere with one type of medium and perfect one's own technique rather than to try a succession of media. It is somewhat surprising that he has made little reference to the recent work of REES and his colleagues at the National Institute of Health on the cultivation of amoebae with single strains of bacteria this *Bulletin* 1946 v. 43: 55 and 1948 v. 45: 60 and the work on the addition of extracts of heat- and otherwise, killed bacteria. Forty-five pages are devoted to the complement fixation tests (C.F.T.) a subject which is very much *sub judice* still although the author has been working on it for at least two decades. He is almost the only worker who has had consistently successful results with his own methods. He finds the test positive in the case of the "symptomatic" carrier and whenever he has encountered a positive result he has usually been able to demonstrate *E. histolytica* cysts in the stool after repeated examinations. It is not clear whether he followed up the negative cases quite as assiduously. He considers that the method of BOZICEVIC, HORRIG and WALSTON is less satisfactory since it usually gives negative results in the case of "carriers". It would be interesting if this question of the C.F.T. in amoebiasis could be settled since its importance goes beyond that of a diagnostic aid. If in fact the C.F.T. is constantly positive in the case of "carriers" it does indicate that there is some tissue invasion in all these cases (the author's view) but if the test is frequently negative it suggests that in many of these cases there is no tissue invasion (the reviewer's opinion).

The author gives a useful critique of diagnostic methods. He considers that the second stool after saline purgation is more likely to contain active amoebae. In the search for cysts he considers that repeated examinations are necessary and recommends the zinc-sulphate centrifugal flotation method with iodine or haematoxylin for staining. He points out that by direct smear examinations less than 1 in 5 individuals will be identified at a single examination and that 10 will have to be negative before a reasonably certain negative report can be given, whereas by the flotation method one in three or four will be positive. He considers that sigmoidoscopy should not be employed as a routine as only rarely will it help in diagnosis when the examination of the stool is negative. [This will come as rather a shock to his modern military school who use the sigmoidoscope as lightly as they use a spatula: the real place of the sigmoidoscope is somewhere between these two extremes.]

Part II (50 pages) is on the laboratory diagnosis of the leishmaniasis. The author gives a very complete and accurate account of this: the main criticism offered is that he has given too many methods and even in his critique of diagnostic methods he has simply repeated what he has said before and has not faced the practical side and given a lead to the worker by indicating when and where the various tests should be used. For example he says "The serological tests employed in the diagnosis of kala-azar are all useful but the most valuable are the complement fixation test, the aldehyde test of Nagler and the antimony tests of Chagas." The C.F.T. can only be carried out in a well-equipped laboratory whereas the aldehyde test can be done in any dry-garage where there is a test-tube and a bottle of formalin. The latter however has very definite limitations and is very little used in the first three months of the disease. Further in hospital practice, the parasite locally may be demonstrated by smear examination or by culture. These facts are not clearly explained. Again it is stated that rectal puncture is safer than liver puncture and is certainly a diagnostic method. About the latter he states

"serious consequences have not been reported", whereas in fact a number of deaths have been reported, and today few experienced workers will agree that it is as certain a diagnostic procedure, though it was fashionable to say so ten years ago. On the subject of peripheral blood cultures, he quotes Knowles as having reported only one positive culture in twelve cases of kala azar. The reviewer does not know where he encountered this statement, but it must have been in a paper written in Knowles's early days, since later he looked upon culture of the peripheral blood as a very reliable method, if the technique was right.

Part III (53 pages) is on the laboratory diagnosis of the trypanosomiasis and Part IV (8 pages) on that of coccidiosis. Part V (90) is on the malarial plasmodia. This is an informative chapter, it includes 6 coloured plates of which three are of the thick-film appearances of malaria parasites taken from Aimee Wilcox's useful manual. There are seven pages devoted to the flocculation tests in malaria which the author takes rather more seriously than do most workers in this field. The last few pages (Part VI—8 pages) are devoted to balantidiasis.

It is a book of limited scope which medical parasitologists will find very useful for reference.

L. E. Napier

RICHARDSON, Ulick F. [B Sc, M R C V S] *Veterinary Protozoology* pp viii+240, 1 coloured pl & 34 figs. 1948. Edinburgh: Oliver and Boyd, Tweeddale Court & London: 98 Great Russell Street, W C. [18/-]

This is the first textbook, so far as the reviewer is aware, to be published in this country dealing exclusively with veterinary protozoology. It consists of some 250 pages and is divided into twelve chapters, the first of which is an interesting general survey of the protozoa affecting man and domestic stock, and deals with the structure, classification and reproduction of the parasitic protozoa as well as with their pathogenicity, the course of the diseases they produce and the immunity or tolerance which sometimes follows such infections. Chapters II–X, which cover 155 pages, are devoted to a systematic description of the various species of pathogenic protozoa and their life-cycles, together with an account of the methods to be adopted for their control and for their eradication from the host. Chapter XI, consisting of 21 pages, is devoted to chemotherapy, although, as previously stated, the treatment of infections due to particular species of parasites is dealt with in the preceding chapters. The twelfth, and last, chapter is an excellent account of the techniques to be adopted for obtaining, examining, and preserving pathological material. At the end of each chapter there is a useful list of references, but many of these are of considerable antiquity. This quoting of work, once of fundamental importance, but now altered by the addition of more recent knowledge, occurs elsewhere in the text, and it is a little surprising to find such statements as (p. 74) 'it has recently been found (Brumpt 1937)', and (p. 127) 'recently attempts have been made by Schilling (1936)'. The reviewer has noticed a few slips in spelling, as (p. 89) 'Louri', and (p. 66) 'Maure's dots'.

The author in his preface states that 'this book has been written in the hope that it may be of value to veterinary students, and to workers in the tropics, where protozoan diseases are the principal problems of the veterinary surgeon, and the chief obstacle to stock improvement'. It is also hoped that it may stimulate interest and lead to research work, which will benefit both veterinary and human medicine. The reviewer has no doubt that the book will stimulate interest in veterinary protozoology to which human medicine already owes so great a debt and it will prove helpful to workers in the tropics, but he has grave misgivings as to the wisdom of using it for the instruction of the inexperienced undergraduate or newly qualified practitioner. The reasons for

these misgivings arise from the fact that the author sometimes present the matter often without comment with a series of views, one or more of which are at variance with the remainder. In addition, he sometimes gives opinions unsupported by convincing evidence which are at conflict with existing belief. The following may be cited as examples of contradictory statements quoted without comment. Having given an account of the life-cycle of *Plasmodium falciparum* including its development in the intestine of the tick, the author on the same page quotes RITCHIE (1936) as saying "there is no development of *Plasmodium falciparum* in the intestines of ticks." Method for the control of *T. parva* (p. 56) occupies three pages and the author having described control by hygienic, then gives two other methods. "All animals in the infected herd are examined daily and any showing fever are slaughtered, the herd being moved to a clean area three times at intervals of fifteen days." Having mentioned reasons for this method and recommended that the area should not be restocked with cattle for eighteen months, he continues "a more drastic method which has met with more success is the slaughter of the whole infected herd, and the abandonment of the grazing ground for cattle for eighteen months." While on the same page under Immunization, he described the classical TWEED (1917) method as follows: "Losses were occasionally heavy up to 30 to 40 per cent, but far less severe than if the disease had spread unchecked. The method does not appear to have been used with success elsewhere." Many similar examples particularly as regard treatment might be quoted from other chapters. To the worker with considerable knowledge of or access to modern literature such divergent opinion are stimulating and interesting, but to the inexperienced student seeking immediate information they are confusing and depressing.

The following may be given as examples of statements at variance with existing beliefs when describing the life-cycle of the malaria parasite in man: the author writes (p. 62) "the parasite is a minute uninucleated organism which enters the blood stream and forces itself into a red blood corpuscle where it increases in size and becomes rounded off." Continuing with the malaria parasite he states (p. 67) "not only are parasitized erythrocytes destroyed but also enormous numbers of unparasitized cells and it may be that the pigment also acts as a haemolytic, and on the same page it has been stated that a mononucleophilic 15 per cent or more is diagnostic of malaria. His views regarding the transmission of human malaria are similarly unwelcome—

"the transmission of the disease may be transmitted by species of *Phlebotomus* not only *P. kerkiri* and *P. papatasi* and by the tick *Hyalomma* as well as *H.* and also probably by *Beetle*" (p. 85).

The existence of a filter-passing stage of trypanosomes is discussed at some length and the author would appear to believe that such a stage exists (p. 103) "this is not the generally accepted view while the former view is no longer evidence to support the statement on p. 101— it is thought that the rate of development of the trypanosome at the time of feeding may influence the infection rate and that for instance no infection with *T. brucei* might occur if no stumpy form were present in the blood. Two other chemotherapeutics which might be mentioned are (p. 201) Pentamidine has not yet been satisfactory in any infection and on p. 128 "In human sleeping sickness the drugs which have failed the test of large scale treatment are antitrypanosomal and trypanocidal." It is generally agreed that pentamidine has become well established for the treatment and prophylaxis of *T. brucei* in man while although trypanocidal has failed the test of time against *T. gambiense* it has not done so against *T. rhodesiense*.

The following will be found well illustrated in the work with the exception of the first paragraph which is correct for the main part in describing the

Book Reviews

Vol 45, No 12]

Mr Richardson's book, which is published at the reasonable price of 18s, should have a considerable sale among veterinary practitioners, as it contains much valuable information which was previously only obtainable by searching through numerous more general textbooks

R M Gordon

BENBROOK, Edward, A [V M D, Professor and Head of the Department of Veterinary Pathology, Iowa State College] & SLOSS, Margaret W [B S, D V M, M S] **Veterinary Clinical Parasitology** 187 pp, 247 figs 1948 Ames, Iowa The Iowa State College Press [\$4 50]

The purpose of this book, as stated in the authors' preface, is "to assist in the diagnosis of parasitism and of parasitic disease by means of laboratory techniques, and to show by illustrations the more commonly encountered forms as well as some of those less often seen."

It is concerned primarily with veterinary parasitology and only three of more important groups of parasites, namely intestinal parasites, parasitic mites and ticks are considered in the present volume. It is stated that if there is a demand for additional chapters, they may be added when sufficient material becomes available, and, to this end, the book is bound in loose-leaf form, so that pages may be added or moved.

The book covers 187 pages of art paper and some 120 of these are occupied with excellent photographs of specific parasites and illustrations of technical methods. The former are clearly marked on each page showing the animal host to which the parasite refers, and this covers a wide range. Seven pages of photographs are given to intestinal parasites of man. Nine pages show illustrations of pseudoparasites or spurious parasites, a most useful guide to microscopists.

The text deals with technical methods in the greatest detail and illustrates the stages of them with very clear photographs. In the second chapter (dealing with mites) and in the third (lice) lists of species and their hosts are also given.

The descriptions of methods of stool examination include the smallest details. There are no less than 20 pages of references, dealing separately with each of the three chapters, and a most comprehensive index of 10 pages. The work is beautifully presented and produced and contains much that the medical parasitologist will find of practical value. It is indeed an excellent book to have on the bench in any parasitological laboratory which deals with the relevant subjects.

H J O D Burke-Gaffney

NAUCK, E G, with ENIGK, K, VOGEL, J, REICHENOW, E, WESTPHAL, A & WEYER, F **Tropical Medicine and Parasitology** Fiat Review of German Science, 1939-1946 253 pp, 8 figs 1948 Published by Office of Military Government for Germany, Field Information Agencies Technical, British, France, U S

The term FIAT is an abbreviation for Field Information Agency, Technical, and the present volume forms one of a series which, in addition to medicine, deals with physics, chemistry, mathematics and sciences of the earth. Well then might it be termed a "Review of Reviews" serving to inform the world of research work on Tropical, Medicine, Hygiene and Parasitology during the war years—from May 1939 to May 1946. This has been accomplished by the co operation of many German contributors, who have furnished the contents while the whole has been prepared for publication by the scientific branches of FIAT. Thus the section on general Tropical Hygiene is by E G NAUCK, on Parasitology by E Reichenow and F WEYER Tropical Diseases

of Man are dealt with by NACKE, REICHENOW, VOGEL, WESTHAAL and WEYER those of domestic animals by H. ENIGK. So condensed is the material that it becomes difficult to convey an idea of the amount of information that this publication contains. Those who look for a detailed account of important investigations do so in vain, but every page gives the impression of endeavouring for knowledge against adversity. The opening pages are indeed a syllabus of the more important German books on tropical medicine and hygiene as well as of the journals devoted to this subject. The best known of these—

Zeitschrift für Schiffs- und Tropenhygiene was, on completion of the 45th volume in 1941 renamed "*Deutsche Tropenmedizinische Zeitschrift*" but on account of war restrictions, it too in June 1944 came to an end and with it the old spirit of enquiry appears to have been temporarily extinguished. A considerable space is devoted to the subject of acclimatization in the tropics to the question of housing and nutrition. The parasitological section, mostly by Reichenow affords a detailed review of protozoology in these war years most of which has found its way into the pages of this *Bulletin* and of course includes the original studies of HILGEMANN, REICHENOW and MUDROW on the erythrocytic cycle of *P. falciparum* and *P. cathemerium*. Other chapters again summarize work done mainly on therapy upon malaria, blackwater fever, leishmaniasis, trypanosomiasis, amoebiasis, spirochaetoses and bacterial diseases, including leprosy and plague. The virus and rickettsial diseases and tropical worm infections also receive attention and there is a contribution on nutritional disorders. The volume is well documented and should continue to serve as a record of hard-won achievement for many years to come.

INDEX OF SUBJECTS

(The entries in heavy type refer to Sections in which abstracts on the subject indicated are grouped together. Page numbers within brackets indicate papers cited by title only.)

Acanthocheilichthys perissus infection

- In Belgian Congo, 100
- Lake Tumba Region, 484
- Lubana, 101
- Port Gange Guinea, 1101
- Southern Sudan, 627

Acacia, or Viter Ticks

Africa, Franco-British Medical Conference at, in 1946, 471

Achomon

- truncata*, causing larva of the mite, 1031
- malcheri* niki, causing larva of the mite, 1031

[*T.*] scholasticus, coexistence of in Jordan, 1031

Actinomyces, tissue changes in, 341*Aedes* spp.

Sickle cell anemia see under Anemia

Simulium of Mexico, 922

Simulium

- control in Kenya, 654
- larvae, factors affecting distribution, (213)
- and transmission of onchocerciasis, 628, (1077), 922
- alt. *ugalis* m. from Lake Tumba Region
- Belgian Congo, 444
- adults, risk of onchocerciasis, 922
- larvae, and onchocerciasis in Southern Sudan, 628

Simulium—cont.

- metallum, vector of onchocerciasis, 922
- onchocercum, vector of onchocerciasis, 922
- Siphunculina fumicola*, suspected vector of tropical ulcer, 1033
- skin reactions to insect bites, 64
- Smallpox
 - in India, 655
 - Morocco, 549
 - air travel and health, gelation, 14
 - control, international of, 11 4
 - endemic foci of, 114
 - immunization certificate, entry of, 14
 - incubation period, 214

Soals

- of Algeria, 98
- Belgian Congo, 115, 348, 1016
- Brazil, 347
- Eritrea, 1017
- French Sudan, 445
- Nyasaland, 618
- Oriental and Western Pacific, 1096
- South Africa, 190
- Southern Rhodesia, 1096
- U.S.A., 913, 914, 1097
- Madagascar, 920

control

- in Algeria, 794
- in island, 618
- Southern Rhodesia, 1096
- Venezuela, 447 448
- chlorobis as poison, diaper to the plant, 527
- copper sulphate, 577
- T. phosphae opus* les. as poison, 618
- hosts of schistosomiasis, 9, 115, 193, 191 19, 192, 359 347 348, 349 445, 577 618, 798, 913, 101 1016, 1017 1096, 1097
- laboratory breeding of, 915

Soaks (see also under V. *boris*, 1011)

Soals

- Echin. armanian* but, 518
- treatment, 1107
- blood transfusion, 34
- carbolic soap solution, 108
- ultra emuls. styrene (341)
- magnesium sulphate, 109
- poisonous
 - African olivaceous, 9 7
 - African per. toxicity of ulcers glands of, 923

Sodium, 603

South Pacific, health services, 1040

SPECIAL ARTICLES, 1 17 1 7 174 377 102, 553 564, 931 844

Spiders

bite of

- in Chile, 104 641
- South Africa, 119
- Lacrodectus*
 - medical treatment, 1107
 - name of, 928
 - lesion to larva, glandular poison of, 109 641
- Spinthum murex*, factu. 60 626

Index of Subjects

Spirochaeta see also *Treponema*
duttoni
 behaviour in monkeys and mice, 710
 preparation of antigen from, 434
 susceptibility of fowl to, 182
 absence of immunity against *S. galli-*
narum 182
 transmission by *Pediculus corporis*, 603
gallinarum absence of immunity against, in
S. duttoni infected birds, 182
hispanica
 loss of infectivity of cultures of, for
O. erraticus 342
 susceptibility of guinea pig to, 710
 transmission by *Ornithodoros* and louse
 603
neotropica, susceptibility of guinea pig to,
 710
recurrentis
 behaviour in monkeys and mice 710
 in cockroaches 91
 susceptibility of guinea pig to 709
venezuelensis susceptibility of guinea pig
 to 710
Spirochaetes
 complications due to splenic abscess 604
 differentiation of African strains of, 86
 710
 tick- from louse borne 709
 Spleen, spontaneous rupture of (932)
 Splenectomy in schistosomiasis 619
 in the tropics, 649
 Splenic circulation microscopic observation of,
 936
Sporotrichosis
 in Brazil 930
 Mexico 542
 diagnosis intradermal reaction 270
 in mice experimental 541
 ocular, treatment 646
 tissue changes in 541
Sporotrichum schenku
 coloured growth on Sabouraud's medium,
 930
 infections with 541 5422
 polysaccharides of 270
SPRUE, 105-107 204 206 357-358 460-462
 535 538 923 924 1026-1027
 in Africa 107
 Assam in troops 205
 Ceylon in troops 205
 Germany in British and Indian
 troops 357
 India in troops 205
 Rhodesia 107
 anaemia and 924
 blood in 535 1026
 bone marrow in 1026
 chylomicron count in 460
 clinical features 205
 diagnosis 204
 fat absorption in 105 106 460 535, 536
 haemopoietic response to vitamin B₁₂ 923
 non tropical, treatment folic acid 205
 para in troops in Burma campaign 357
 salt deficiency in, 106
 serum lipides in 204
 steatorrhoea in 105
 aetiology of 105

Sprue—cont

syndrome, 1026
 treatment
 folic acid, 106 107, 206, 358, 360, 460, 461,
 536
 neurologic changes following, 536
 liver extract, 106
 nicotinic acid, 106
 pteroylglutamic acid, 461 (538)
 riboflavin, 106
 sulphaguanidine, 205
 vitamin B₁₂ 923
 yeast extract, 106
Stilbamidine
 excretion of, in experimental animals, 56
 instability of, 775
 toxicity of, 164
Streptobacillus moniliformis septicaemia, 605
 Streptococcal infections in Central African
 natives, 212
Streptococcus viridans tropical primary phle-
 bitis and 545
Strongyloides
fülleborni in man, 722
stercoralis infection
 in Brazil 801
 Spain, (800)
 geographical races of, 801
 Strongyloidosis, associated with schistoso-
 miasis and syphilis, (351)
 Surgical aspects of intestinal parasitism, 469
 Sweat, loss of, salt tablets to combat, 112
Syngamus laryngeus human infestation with,
 1100
Syntomosphyrum glossinae parasitizing *Glos-*
sinae in Nigeria, 245
 Syphilis
 in Uganda, 544
 and false positive serological reactions in
 malaria 30 31, 1056
 strongyloidosis associated with (351)
 Tabanidae, African notes on type-specimens,
 119
Taeniasis see under Tapeworm infection
Taeniorhynchus
filariae found in 1101
africanus filaria found in 1129
chrysonotum flight range experiments with,
 1081
fasciolatus flight range experiments with
 1081
 Tapeworm infection (see also Hydatid disease)
 Diphyllbothridae, larval, aseptic cultivation
 of, (350)
Diphyllbothrium latum infection
 in Finland, 198 260, 449 450 920
 anaemia
 cryptogenetic pernicious 260
 hypochromic, 449
 pernicious tapeworm 97, 198 260 450
 920 1098
 urobilin excretion in 1098
 diagnosis
 differential, of pernicious tapeworm and
 cryptogenetic pernicious
 anaemia in 260
 staining of ova 449
 site of infestation in intestine 198 260
 staining of ova 449

T. parvum infection—cont.

- Hymenolepis*
infection in Mexico, 1119
dominant infection
in Uruguay (98)
in *Rattus norvegicus*, 1019
murine infection
in *Rattus norvegicus*, 1019
new infection
in Italy Milan rural population, 530
as *frankina* infection in alcoholic mice,
reduced food intake and 98

T. parvum infection

- in Kenya, T. etc. 672
and *T. solium* infection in Mexico, 1119
poisoning of mice by extract of,
(350)
thermal death point of *Cysticercus* of, 97
treatment
stomach tube (Stomach), 921
in (Solitaris) Cuba, 1099

T. parvum

- in Mexico, 261
treatment, 761
benzene, 807
normal case of, (350)

T. parvum

- phases, solid, less of, use in small de-
struction, 618

T. parvum

- Thiamine of milled raw and parboiled rice,
204

Thrombophlebitis, idiopathic, 543, 546

T. parvum

- of Madagascar (1122)
South Africa, (935)

T. parvum

- arsenic-resistant, control with BHC dips, 274
rules of, cutaneous reactions in, 642
control
BHC, 774, 114
DDT 114
EGOS E, 114

T. parvum

- newer synthetic insecticides, 1123
repellents, tests with impregnated clothing,
114, 654

T. parvum

- immunity to acquired, experimental investi-
gation of, 114

T. parvum

- man's toxicity to, 652
phototactic and phototropic responses of,
114

T. parvum

- parasites, are *Cryptococcus*
parasites of French Sudan, ethiopia plus mes-
sion in, (655)

T. parvum

- parasitism
cultivation of, 1035
in guinea pigs in Adhis Ababa, 12
isolation of from the tropical band during
life, 1036

T. parvum

- morphology of, 117
neutralizing antibodies in various disease
conditions, 650

T. parvum

- new cult. of, 368
replasmids
in Europe, 369
Holland, 369, 1036
Switzerland, 369
U.S.A., 369, 470

T. parvum

- symptoms, 470
original, 650
discovery, 1036
morphology and, 368, 369

T. parvum

- ocular manifestations in, 469
virus infection in, 114

T. parvum

- in Cape Verde Islands, 1114
China, 1109, 1111

T. parvum

- treatment, sulphamide, 646
urea, cultivation in 1/2 lit. of beer, 357,
1112

T. parvum

- Trepone*, or also *Sporothrix*
curriculum causing pneumonia, 363

T. parvum

- delphonet* map, naturally infected by
S. etc., 314

T. parvum

- infections
symptoms of bacteria in, (935)
transmitting Chagas disease in Bolivia,
413

T. parvum

- peritrichi*, in Mexico, 163
proctos, only, in Mexico, 163
retroflexus, not used by T. p.
morphology, 417

T. parvum

- Trichinosis of Brazil, Abiqua, 116
Trichinosis, effects of labour migration on, 82

T. parvum

- Trichinosis of *peritrichi*, operation for, 1111

T. parvum

- Trichinella spiralis*
bacteria from Porto Rican rats, (923)
nigra, skin tests etc. on population of
Okinawa, 453

T. parvum

- infection, 355
covered from intestine of man, 451

T. parvum

- in Chile, in military training school,
356

T. parvum

- England, 355
incidence (found at best part,
355)

T. parvum

- U.S.A., in German prisoners of war,
356

T. parvum

- Uruguay (10.3)
control, (774)
intestinal phase of, 457

T. parvum

- dermatologic complications of, 630
symptoms, (357)
treatment, experimental, between, 513

T. parvum

- Trichomonas, species of, in man, 116
trichomonad flagellates, host relationships of,
117

T. parvum

- Trichophyton ferrugineum*
in A. etc., 1130
not found in S. etc., Cape Verde
Islands, 1130

T. parvum

- Trichostomum* infection
in A. etc., 99
identification of some species of, (351)
in man, 802
as infection, in man, 99
of *Trichostomum* etc. etc. in man in A. etc., 99

T. parvum

- Trichostema* *ultracoma*, or *ultracoma* of *ultracoma*
etc. etc., 833

T. parvum

- Trichuris trichiura* (Leish)
in Brazil, 347, 629
C. etc. in P.O.W. from Hong
Kong, 517
Cape Verde Islands, 1130
French Guinea, 627
Italy, Milan rural population, 530
intestinal structure, etc. in female, 163

- Tritrachium brumpti* and the genus *Tritrachium*, 111
- Trombicula acuscutellaris* rearing of 548
akamishi 'bites' of cutaneous reaction to, 642
- deliensis*
 in Maldive Islands, 216
 short feeding time of, 67
- Trombiculid* mites
 biology of, in relation to disease, 66
 collected in Imphal and Kumaon Hills, 69
 control
 benzene hexachloride 326
 phthalates 651
 on eyelid, 646
 feeding time of 67
 rearing of 120
- Tropical diseases**
 in Touat Central Sahara 818
 advances in treatment of (126)
 development of pathology of, (649)
 lymph node in, 114
 nervous system in 1034
 fatigue and warfare 1114
 hygiene, information on, (658)
 Institute Hamburg activities of 375
 medicine
 in Germany (126)
 Institute at Lisbon (1043)
 Netherlands Association for 736
 practice of in London 374
 Scottish pioneers in 820
 neurology, plasma permeability of choroidal barrier in, 544
- Tropicorbis* sp.
 experimentally infected with schistosomes 445
havensis experimental infection with *Schistosoma mansoni* 913
- Trypanosoma**
brucei
 chemoprophylaxis 1072
 cross immunity with *T. gambiense* 503
 experimental transmission to man 504
 natural infections with in a *G. palpalis* area 503
 p rosaniline resistant strain of persistence of parabasal body in, 503
 phylogenetic relations of trypanosomes of *brucei* group 586
 T. gambiense and *T. rhodesiense* recorded as mutant variants 586
 rates of infection of wild tsetse 414
 relationship to *T. evansi* 505 690
 to *T. gambiense* and *T. rhodesiense* 586
- congolense*
 in elphants 414
 rates of infection of wild tsetse 414
 transmissibility of affected by temperature 414
- crassicauda*
 cultivation on NNN medium 417
 infecting rat in Brazil 417
 infection of *Trypanosoma* in Brazil 417
- Trypanosoma—cont**
cruzi
 action of endotoxin on mouse tumour, (692) (881)
 biochemical activities in culture of, 774
 cultivation of, 880 1073
 in dialysate medium, 880
 tissue culture technique 983
 endotoxin in treatment of mouse tumours, (692) (881)
 respiration of, 774
 serological reactions specificity of, 590
duttoni fate in *Triatoma* (790)
equinum prophylactic action of pentamidine, 879
- equiperdum*
 chemoprophylaxis, 1072
 effect of nitrogen mustard on, antagonising action of cysteine, 692
 infection in rats, effect of glucose on, 505
 lysed, effect of drugs on activity of glycolytic enzymes, 773
 micromanipulation of virulence of single or several trypanosomes, 587
 phosphorus metabolism of 587
 prophylactic action of pentamidine 879
 staining reactions of normal and drug resistant strains, 313
 sulphydryl and disulphide content of arsenic resistant strain 690
 treatment Furacin 52
- evansi*
 chemoprophylaxis 1072
 control, in U.S.S.R. 689
 failure to develop in *G. morsitans* 690
 glucose metabolism of effect on trypanocides 495
 relationship to *T. brucei* 505 690
- gambiense*
 enhancement of virulence of old strain of, 585
 micromanipulation of virulence of single or several trypanosomes 587
 Yaoundé strain chemoprophylaxis, 1071
- happicum*
 staining reactions of normal and drug resistant strains 313
 sulphydryl and disulphide content of arsenic resistant 690
- lewisii*
 experimental studies on 417
 glucose metabolism of (1074)
 infection in pantothenate deficient rats liver changes, 773
 influence of biotin deficiency on infection with, 417
 inhibition of reproduction by immune factors 1121
 oxidative metabolism of in phosphate saline medium, (1074)
- rancho* human cultivated from peripheral blood 1972
- rhodesiense*
 experimental infection of rats relative to electrical charge 50
 electrical charge in relation to 50

T. parva—cont.

Antenae—cont.

- length distributions in relation to infection, 40
- prolonged experimental infection in warble flies and chloids, 414
- transmissibility of, affected by temperature, 414

Anatomy

- morphology of metacyclic forms, 313
- polymorphism in, 313
- series of infection of wild tsetse, 414
- transmission, mechanical, by body flies in tsetse-free areas, 505

Trypanosomes, infections produced by single, 587
